Phys. Rev. Lett. **113**, 076802 – Published 13 August 2014

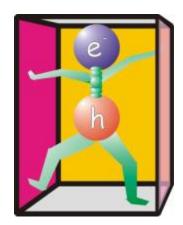

Why Study Monolayer WS₂?

- Model transition-metal dichalcogenide (TMD)
 - Large splitting between A and B excitons means no overlap between them
- 2D properties of TMDs show promise
 - Carrier concentration easily controllable with light
 - Possible because of direct bandgap

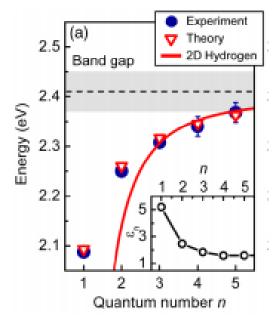

Measuring the exciton binding energies

- Researchers shined linearly polarized light on monolayer WS₂
- Measured the reflectance of light at various energies in order to measure the energy level of excited excitons

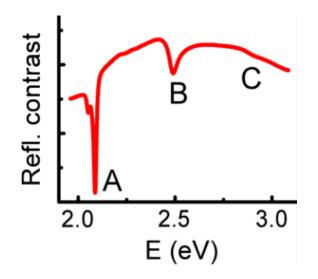

Excitonic energies don't show hydrogenic behavior

- Plotted observed exciton energy levels
 - Did not observe the expected hydrogenic energy spectrum
- Calculated a band gap of 0.32 eV

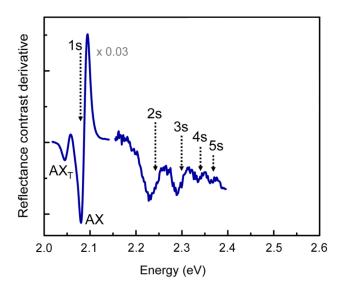

Measurements of Reflectivity Contrast Peaks

Reflectance contrast of monolayer WS₂ measured

Calculated derivative

 Shows peaks more clearly

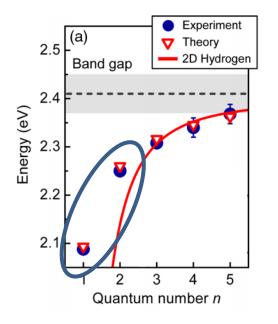

Fitting Binding Energies to Hydrogenic Hamilton

Fit energies of Rydberg excitons to hydrogenic Hamiltonian

$$H = -\frac{\hbar^2}{2\mu} \nabla^2 - \frac{e^2}{\varepsilon r}$$

$$E = E_g - E_b^n$$

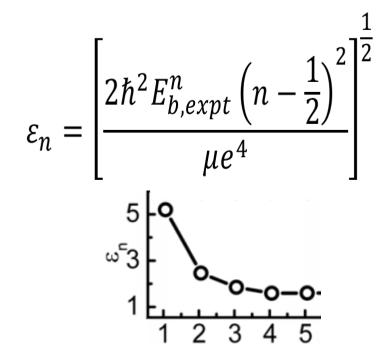

$$E_b^n = \frac{\mu e^4}{2\hbar^2 \varepsilon^2 \left(n - \frac{1}{2}\right)^2}$$

Fitted value of E_g is 2.41eV Gives value for E_b as 0.32eV

Energy Levels Don't Match Hydrogenic Hamiltonian

Recalculate ε as function of n

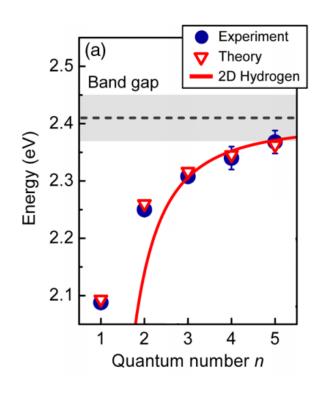

Use a different potential form to account for antiscreening in monolayer

$$V(r) = -\frac{\pi e^2}{2r_0} \left[H_0\left(\frac{r}{r_0}\right) - Y_0\left(\frac{r}{r_0}\right) \right]$$

Provides the necessary long range 1/r behavior, but alters the short range potential primarily

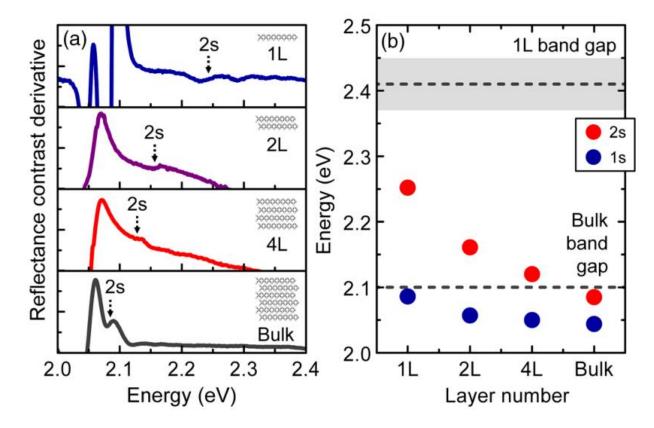

Fitting the Experimental Data with New Hamiltonian

Fitting parameters r_0 and E_g are calculated to be 75Å and 2.41eV

Gives 1s exciton binding energy of 0.32eV – accurate with experiment

Number of Layers Changes the Energy and Number of Exciton Excitations

Primarily a monolayer effect, very quickly drops off with increasing thickness

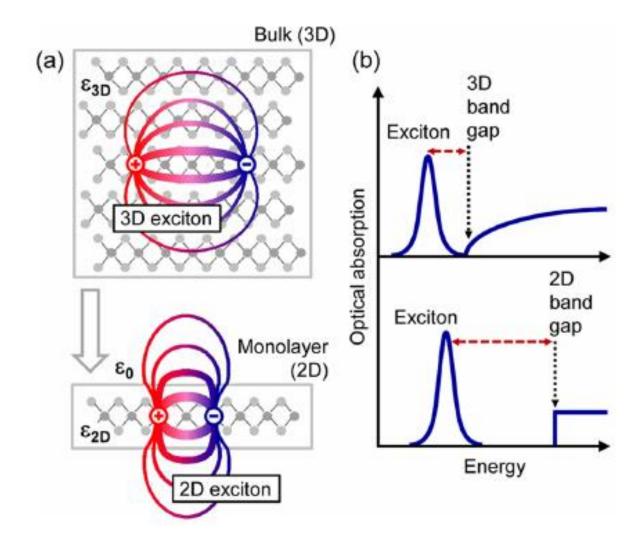

Review of Important Ideas

- Authors used reflectance to determine exciton binding energy in WS₂
- Energy levels for n > 2 resemble Hydrogen energy levels (Rydberg series)
- Deviations well-explained by screening effects

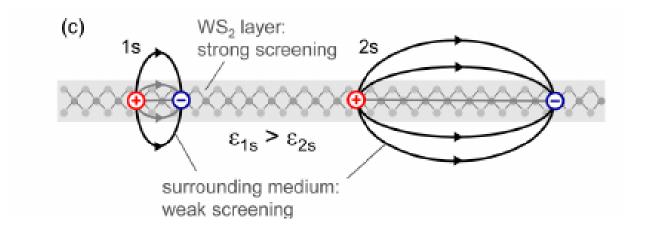

Are these properties universal?

- Authors want to understand properties of TMDs
- Do their results extend to other such materials?
 - Nonhydrogenic model derived based on geometry of system
 - Should be universally applicable to similar monolayers

Why results might apply to other 2D materials

Screening Depends on the Size of the Exciton

- Larger excitons/higher n values, the electric field exists significantly outside the monolayer
 - Lowers the screening

High Binding Energy

Non-hydrogenic behavior and high binding energy (0.32 eV) common in 2D TMDs

Implies high thermal stability

Potential applications in optoelectronics in visible range

Higher order effects likely to be important (trion and biexiton formation)

Critiques of the Paper

- Well-written paper gives especially good introduction and qualitative descriptions
- Much supplementary material (including setup)
- Measured relative reflectance, reported its energy derivative
- Not specified how to obtain energy levels from this measurement
- Errors given without explanation

Citation Analysis: Basic Facts

• "Birthday" : August 13, 2014

- 87 Citations so far (via SCOPUS)
 - 78 in 2015

Citation Context Within Field

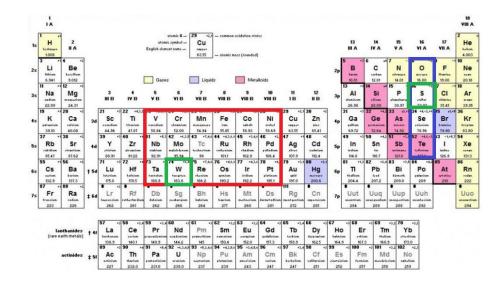

• Out of 87 citations, 75 are independent of the Columbia/ Brookhaven group

- Cited 6 times each by Berkeley
- Citations of Citations

Evolution of the Field

- Two Main Paths
 - -2D layers in general
 - Excitons in very similar materials (MoS2,ReS2,WSe2)

Similar Subsequent Studies

 Exciton Binding Energy of Monolayer WS2(Keliang He, Nardeep Kumar, et al.)

- studies trion binding energy, exciton-exciton annihilation

 Probing Excitonic Dark States in Single-layer Tungsten Disulfide(Ziliang Ye, Ting Cao, et al.)

- studies dark states that do not absorb/transmit photons

 Non-linear Optical Spectroscopy of Excited Exciton States for Efficient Valley Coherence Generation in WSe2 Monolayers(G. Wang, X. Marie, et al.)

- studies valley coherence (electron states at band edges)

Similar Studies

- Optically bright *p*-excitons indicating strong Coulomb coupling in transition-metal dichalcogenides(Tineke Stroucken, Stephan W. Koch)
 - experimentally compares resonance energies with computed values
 - optically bright excitonic transitions have *p*-like symmetry
- Tightly Bound Excitons in Monolayer WSe2 (Keliang He, Nardeep Kumar, et al.)
 - excited exciton states even at room temperature

Authors' Continued Interest

• Recent Paper Titles

-Binding energies and spatial structures of small carrier complexes in monolayer transition-metal dichalcogenides via diffusion Monte Carlo

-Electrical Tuning of Exciton Binding Energies in Monolayer WS2

-Observation of excitonic Rydberg states in monolayer MoS2 and WS2 by photoluminescence excitation spectroscopy

-Observation of biexcitons in monolayer WSe 2

Future of the Field

- 2D materials are in high demand
 - relatively young field (c. 2004)
 - Graphene studies win 2010 Nobel Prize (Andre Geim, Konstantin Novoselov)
- Applications to technology
 - WS2 offers large binding energy, band gap
 - 2D features:
 - Coulomb interaction enhancement
 - many-body physics
 - high performance field effect transistors
