

# Probability and Statistics for Computer Science

“All models are wrong, but some models are useful” --- George Box

Credit: wikipedia

# Last time

- ✱ Linear regression
  - ✱ The problem
  - ✱ The least square solution
  - ✱ The training and prediction
  - ✱ The R-squared for the evaluation of the fit.

# Objectives

- ✱ Linear regression (cont.)
  - ✱ Modeling non-linear relationship with linear regression
  - ✱ Outliers and over-fitting issues
  - ✱ Regularized linear regression/Ridge regression
- ✱ Nearest neighbor regression

# What if the relationship between variables is non-linear?

- ✱ A linear model will not produce a good fit if the dependent variable is **not** linear combination of the explanatory variables

Frequency of word usage in Shakespeare

# Transforming variables could allow linear model to model non-linear relationship

- ✱ In the word-frequency example, log-transforming both variables would allow a linear model to fit the data well.

Frequency of word usage in Shakespeare, log-log

# More example: Data of fish in a Finland lake

- ✧ Perch (a kind of fish) in a lake in Finland, 56 data observations
- ✧ Variables include: Weight, Length, Height, Width
- ✧ In order to illustrate the point, let's model **Weight** as the dependent variable and the **Length** as the explanatory variable.

Yellow Perch

# Is the linear model fine for this data?

A. YES

B. NO

Weight vs length in perch from Lake Laengelmavesi

# Is the linear model fine for this data?

- ✱ R-squared is 0.87 may suggest the model is OK
- ✱ But the trend of the data suggests non-linear relationship
- ✱ Intuition tells us length is not linear to weight given fish is 3-dimensional
- ✱ We can do better!

Weight vs length in perch from Lake Laengelmavesi

# Transforming the explanatory variables

Weight vs length<sup>3</sup> in perch from Lake Laengelmavesi

Weight predicted from length<sup>3</sup> in perch from Lake Laengelmavesi

Q. What are the matrix  $X$  and  $y$ ?

1	Length <sup>3</sup>	Weight

# Transforming the dependent variables

Weight<sup>(1/3)</sup> vs length in perch from Lake Laengelmavesi

Weight<sup>(1/3)</sup> predicted from length in perch from Lake Laengelmavesi

What is the model now?

# What are the matrix $X$ and $y$ ?

1	Length	$\sqrt[3]{w}$
---	--------	---------------

# Effect of outliers on linear regression

✿ Linear regression is sensitive to outliers

# Effect of outliers: body fat example

- ✿ Linear regression is sensitive to outliers

Weight against height, all points

Weight against height, 4 outliers removed

# Over-fitting issue: example of using too many power transformations

Weight vs length in perch from Lake Laengelmavesi, three models.

Weight vs length in perch from Lake Laengelmavesi, all powers up to 10.

# Avoiding over-fitting

## \* **Method 1: validation**

- \* Use a validation set to choose the transformed explanatory variables
- \* The difficulty is the number of combination is exponential in the number of variables.

## \* **Method 2: regularization**

- \* Impose a penalty on complexity of the model during the training
- \* Encourage smaller model coefficients
- \* We can use validation to select regularization parameter  $\lambda$

# Regularized linear regression

- ✱ In ordinary least squares, the cost function is  $\|\mathbf{e}\|^2$ :

$$\|\mathbf{e}\|^2 = \|\mathbf{y} - X\boldsymbol{\beta}\|^2 = (\mathbf{y} - X\boldsymbol{\beta})^T (\mathbf{y} - X\boldsymbol{\beta})$$

- ✱ In regularized least squares, we add a penalty with a weight parameter  $\lambda$  ( $\lambda > 0$ ):

$$\|\mathbf{y} - X\boldsymbol{\beta}\|^2 + \lambda \frac{\|\boldsymbol{\beta}\|^2}{2} = (\mathbf{y} - X\boldsymbol{\beta})^T (\mathbf{y} - X\boldsymbol{\beta}) + \lambda \frac{\boldsymbol{\beta}^T \boldsymbol{\beta}}{2}$$

# Training using regularized least squares

- ✱ Differentiating the cost function and setting it to zero, one gets:

$$(X^T X + \lambda I)\boldsymbol{\beta} - X^T \mathbf{y} = 0$$

- ✱  $(X^T X + \lambda I)$  is always invertible, so the regularized least squares estimation of the coefficients is:

$$\hat{\boldsymbol{\beta}} = (X^T X + \lambda I)^{-1} X^T \mathbf{y}$$

# Why is the regularized version always invertible?

**Prove:**  $(X^T X + \lambda I)$  is invertible ( $\lambda > 0$ ,  $\lambda$  is not the eigenvalue).

Energy based definition of **semi-positive definite**:

Given a matrix  $A$  and any nonzero vector  $f$ , we have

$$f^T A f \geq 0$$

and **positive definite** means

$$f^T A f > 0$$

If  $A$  is positive definite, then all eigenvalues of  $A$  are positive, then it's invertible

# Why is the regularized version always invertible?

Prove:  $(X^T X + \lambda I)$  is invertible ( $\lambda > 0$ ,  $\lambda$  is not the eigenvalue).

$$f^T A f \geq 0$$

$$f^T A f > 0$$

# Over-fitting issue: example from using too many power transformations

Weight vs length in perch from Lake Laengelmavesi, three models.

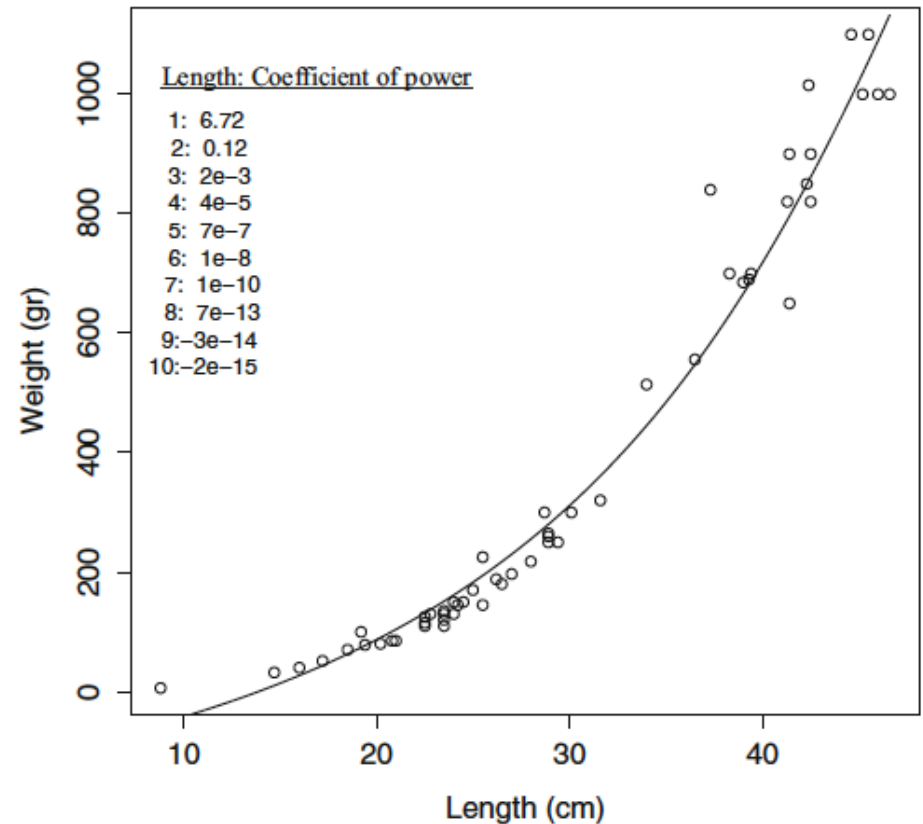

Weight vs length in perch from Lake Laengelmavesi, all powers up to 10.

# Choosing lambda using cross-validation

Weight vs length in perch from Lake Laengelmavesi, all powers up to 10, regularized

Q. Can we use the R-squared to evaluate the regularized model correctly?

A. YES

B. NO

C. YES and NO

# Nearest neighbor regression

- ✱ In addition to linear regression and generalize linear regression models, there are methods such as **Nearest neighbor regression** that do not need much training for the model parameters.
- ✱ When there is plenty of data, nearest neighbors regression can be used effectively

# K nearest neighbor regression with $k=1$

The idea is very similar to k-nearest neighbor classifier, but the regression model predicts numbers

$K=1$  gives piecewise constant predictions

# K nearest neighbor regression with weights

The goal is to predict  $y_0^p$  from  $\mathbf{x}_0$  using a training set  $\{(\mathbf{x}, y)\}$

- ✱ Let  $\{(\mathbf{x}_j, y_j)\}$  be the set of  $k$  items in the training data set that are closest to  $\mathbf{x}_0$ .
- ✱ Prediction is the following:

$$y_0^p = \frac{\sum_j \mathbf{w}_j y_j}{\sum_j \mathbf{w}_j}$$

Where  $\mathbf{w}_j$  are weights that drop off as  $\mathbf{x}_j$  gets further away from  $\mathbf{x}_0$ .

# Choose different weights functions for KNN regression

$$y_0^p = \frac{\sum_j \mathbf{w}_j y_j}{\sum_j \mathbf{w}_j}$$

✱ Inverse distance

$$\mathbf{w}_j = \frac{1}{\|\mathbf{x}_0 - \mathbf{x}_j\|}$$

✱ Exponential function

$$\mathbf{w}_j = \exp\left(-\frac{\|\mathbf{x}_0 - \mathbf{x}_j\|^2}{2\sigma^2}\right)$$

# Evaluation of KNN models

- ✱ Which methods do you use to choose  $K$  and weight functions?
- A. Cross validation
  - B. Evaluation of MSE
  - C. Both A and B

# The Pros and Cons of K nearest neighbor regression

## ✱ Pros:

- ✱ The method is very intuitive and simple
- ✱ You can predict more than numbers as long as you can define a similarity measure.

## ✱ Cons

- ✱ The method doesn't work well for very high dimensional data
- ✱ The model depends on the scale of the data
