

## 17.2

### Breadth First Search

# Breadth First Search (BFS)

## Overview

- Ⓐ **BFS** is obtained from **BasicSearch** by processing edges using a queue data structure.
- Ⓑ It processes the vertices in the graph in the order of their shortest distance from the vertex **s** (the start vertex).

## As such...

- ① **DFS** good for exploring graph structure
- ② **BFS** good for exploring distances

# xkcd take on DFS

# Queue Data Structure

## Queues

A **queue** is a list of elements which supports the operations:

- 1 **enqueue**: Adds an element to the end of the list
- 2 **dequeue**: Removes an element from the front of the list

Elements are extracted in **first-in first-out (FIFO)** order, i.e., elements are picked in the order in which they were inserted.

# BFS Algorithm

Given (undirected or directed) graph  $G = (V, E)$  and node  $s \in V$

## **BFS(s)**

Mark all vertices as unvisited

Initialize search tree  $T$  to be empty

Mark vertex  $s$  as visited

set  $Q$  to be the empty queue

**enqueue**( $Q, s$ )

**while**  $Q$  is nonempty **do**

$u =$  **dequeue**( $Q$ )

**for** each vertex  $v \in \text{Adj}(u)$

**if**  $v$  is not visited **then**

            add edge  $(u, v)$  to  $T$

            Mark  $v$  as visited and **enqueue**( $v$ )

## Proposition

**BFS(s)** runs in  $O(n + m)$  time.
