## CS 473: Algorithms, Fall 2019

## Universal and Perfect Hashing

Lecture 10
September 26, 2019

## Announcements and Overview

- Pset 4 released and due on Thursday, October 3 at 10am. Note one day extension over usual deadline.
- Midterm 1 is on Monday, Oct 7th from 7-9.30pm. More details and conflict exam information will be posted on Piazza.
- Next pset will be released after the midterm exam.

## Announcements and Overview

- Pset 4 released and due on Thursday, October 3 at 10am. Note one day extension over usual deadline.
- Midterm 1 is on Monday, Oct 7th from 7-9.30pm. More details and conflict exam information will be posted on Piazza.
- Next pset will be released after the midterm exam.

Today's lecture:

- Review pairwise independence and related constructions
- (Strongly) Universal hashing
- Perfect hashing

## Part I

## Review

## Pairwise independent random variables

## Definition

Random variables $X_{1}, X_{2}, \ldots, X_{n}$ from a range $B$ are pairwise independent if for all $\mathbf{1} \leq \boldsymbol{i}<\boldsymbol{j} \leq \boldsymbol{n}$ and for all $\boldsymbol{b}, \boldsymbol{b}^{\prime} \in B$,

$$
\operatorname{Pr}\left[X_{i}=b, X_{j}=b^{\prime}\right]=\operatorname{Pr}\left[X_{i}=b\right] \cdot \operatorname{Pr}\left[X_{j}=b^{\prime}\right] .
$$

## Constructing pairwise independent rvs

Suppose we want to create $\boldsymbol{n}$ pairwise independent random variables in range $\mathbf{0}, \mathbf{1}, \ldots, \boldsymbol{m}-\mathbf{1}$. That is we want to generate $X_{0}, X_{2}, \ldots, X_{n-1}$ such that

- $\operatorname{Pr}\left[X_{i}=\alpha\right]=1 / m$ for each $\alpha \in\{0,1,2, \ldots, m-1\}$
- $\boldsymbol{X}_{\boldsymbol{i}}$ and $\boldsymbol{X}_{\boldsymbol{j}}$ are independent for any $\boldsymbol{i} \neq \boldsymbol{j}$

## Constructing pairwise independent rvs

Suppose we want to create $\boldsymbol{n}$ pairwise independent random variables in range $\mathbf{0 , 1}, \ldots, \boldsymbol{m}-\mathbf{1}$. That is we want to generate $X_{0}, X_{2}, \ldots, X_{n-1}$ such that

- $\operatorname{Pr}\left[X_{i}=\alpha\right]=1 / m$ for each $\alpha \in\{0,1,2, \ldots, m-1\}$
- $\boldsymbol{X}_{\boldsymbol{i}}$ and $\boldsymbol{X}_{\boldsymbol{j}}$ are independent for any $\boldsymbol{i} \neq \boldsymbol{j}$

Interesting case: $\boldsymbol{n}=\boldsymbol{m}=\boldsymbol{p}$ where $\boldsymbol{p}$ is a prime number

- Pick $a, b$ uniformly at random from $\{0,1,2, \ldots, p-1\}$
- Set $X_{i}=a i+b$
- Only need to store $\boldsymbol{a}, \boldsymbol{b}$. Can generate $\boldsymbol{X}_{\boldsymbol{i}}$ from $\boldsymbol{i}$.

## Constructing pairwise independent rvs

Suppose we want to create $\boldsymbol{n}$ pairwise independent random variables in range $\mathbf{0 , 1}, \ldots, \boldsymbol{m}-\mathbf{1}$. That is we want to generate $X_{0}, X_{2}, \ldots, X_{n-1}$ such that

- $\operatorname{Pr}\left[X_{i}=\alpha\right]=1 / m$ for each $\alpha \in\{0,1,2, \ldots, m-1\}$
- $\boldsymbol{X}_{\boldsymbol{i}}$ and $\boldsymbol{X}_{\boldsymbol{j}}$ are independent for any $\boldsymbol{i} \neq \boldsymbol{j}$

Interesting case: $\boldsymbol{n}=\boldsymbol{m}=\boldsymbol{p}$ where $\boldsymbol{p}$ is a prime number

- Pick $a, b$ uniformly at random from $\{0,1,2, \ldots, p-1\}$
- Set $X_{i}=a i+b$
- Only need to store $\boldsymbol{a}, \boldsymbol{b}$. Can generate $X_{i}$ from $\boldsymbol{i}$.

Relies on the fact that $\mathbb{Z}_{\boldsymbol{p}}=\{0,1,2, \ldots, p-1\}$ is a field

## Pairwise independence for general n and m

A rough sketch.
If $\boldsymbol{n}<\boldsymbol{m}$ we can use a prime $\boldsymbol{p} \in[\boldsymbol{m}, \mathbf{2 m}]$ (one always exists) and use the previous construction based on $\mathbb{Z}_{\boldsymbol{p}}$.
$\boldsymbol{n}>\boldsymbol{m}$ is the more difficult case and also relevant.

The following is a fundamental theorem on finite fields.

## Theorem

Every finite field $\mathbb{F}$ has order $\boldsymbol{p}^{\boldsymbol{k}}$ for some prime $\boldsymbol{p}$ and some integer $\boldsymbol{k} \geq \mathbf{1}$. For every prime $\boldsymbol{p}$ and integer $\boldsymbol{k} \geq \mathbf{1}$ there is a finite field $\mathbb{F}$ of order $\boldsymbol{p}^{\boldsymbol{k}}$ and is unique up to isomorphism.

We will assume $\boldsymbol{n}$ and $\boldsymbol{m}$ are powers of $\mathbf{2}$. From above can assume we have a field $\mathbb{F}$ of size $n=2^{k}$.

## Pairwise independence when $\mathrm{n}, \mathrm{m}$ are powers of 2

We will assume $\boldsymbol{n}$ and $\boldsymbol{m}$ are powers of $\mathbf{2}$.
We have a field $\mathbb{F}$ of size $n=2^{k}$.
Generate $n$ pairwise independent random variables from [ $n$ ] to $[n$ ] by picking random $a, b \in \mathbb{F}$ and setting $X_{i}=\boldsymbol{a}+\boldsymbol{b}$ (operations in $\mathbb{F}$ ). From previous proof $X_{1}, \ldots, X_{n}$ are pairwise independent.

Now $X_{i} \in[n]$. Truncate $X_{i}$ to [ $m$ ] by dropping the most significant $\log \boldsymbol{n}-\log \boldsymbol{m}$ bits. Resulting variables are still pairwise independent (both $\boldsymbol{n}, \boldsymbol{m}$ being powers of $\mathbf{2}$ important here).

Skipping details on computational aspects of $\mathbb{F}$ which are closely tied to the proof of the theorem on fields.

## Pairwise Independence and Chebyshev's Inequality

## Chebyshev's Inequality

For $a \geq 0, \operatorname{Pr}[|X-\mathrm{E}[X]| \geq a] \leq \frac{\operatorname{Var}(X)}{a^{2}}$ equivalently for any $t>0, \operatorname{Pr}\left[|X-\mathrm{E}[X]| \geq t \sigma_{X}\right] \leq \frac{1}{t^{2}}$ where $\sigma_{X}=\sqrt{\operatorname{Var}(X)}$ is the standard deviation of $\boldsymbol{X}$.

Suppose $X=X_{1}+X_{2}+\ldots+X_{n}$. If $X_{1}, X_{2}, \ldots, X_{n}$ are independent then $\operatorname{Var}(X)=\sum_{i} \operatorname{Var}\left(X_{i}\right)$.

## Pairwise Independence and Chebyshev's Inequality

## Chebyshev's Inequality

For $a \geq 0, \operatorname{Pr}[|X-\mathbf{E}[X]| \geq a] \leq \frac{\operatorname{Var}(X)}{a^{2}}$ equivalently for any $t>0, \operatorname{Pr}\left[|X-\mathrm{E}[X]| \geq t \sigma_{X}\right] \leq \frac{1}{t^{2}}$ where $\sigma_{X}=\sqrt{\operatorname{Var}(X)}$ is the standard deviation of $\boldsymbol{X}$.

Suppose $X=X_{1}+X_{2}+\ldots+X_{n}$. If $X_{1}, X_{2}, \ldots, X_{n}$ are independent then $\operatorname{Var}(X)=\sum_{i} \operatorname{Var}\left(X_{i}\right)$.

## Lemma

Suppose $\boldsymbol{X}=\sum_{i} X_{i}$ and $X_{1}, X_{2}, \ldots, X_{n}$ are pairwise independent, then $\operatorname{Var}(X)=\sum_{i} \operatorname{Var}\left(X_{i}\right)$.

Hence pairwise independence suffices if one relies only on Chebyshev inequality.

## Part II

## Hash Tables

## Dictionary Data Structure

(1) $\mathcal{U}$ : universe of keys with total order: numbers, strings, etc.
(2) Data structure to store a subset $S \subseteq \mathcal{U}$
(3) Operations:
(1) Search/look up: given $x \in \mathcal{U}$ is $x \in S$ ?
(2) Insert: given $x \notin S$ add $x$ to $S$.
(3) Delete: given $x \in S$ delete $x$ from $S$
(9) Static structure: $S$ given in advance or changes very infrequently, main operations are lookups.
(5) Dynamic structure: $S$ changes rapidly so inserts and deletes as important as lookups.

Can we do everything in $O(1)$ time?

## Hashing and Hash Tables

Hash Table data structure:
(1) A (hash) table/array $\boldsymbol{T}$ of size $\boldsymbol{m}$ (the table size).
(2) A hash function $h: \mathcal{U} \rightarrow\{0, \ldots, m-1\}$.
(3) Item $x \in \mathcal{U}$ hashes to slot $h(x)$ in $T$.

## Hashing and Hash Tables

Hash Table data structure:
(1) A (hash) table/array $\boldsymbol{T}$ of size $\boldsymbol{m}$ (the table size).
(2) A hash function $h: \mathcal{U} \rightarrow\{0, \ldots, m-1\}$.
(3) Item $x \in \mathcal{U}$ hashes to slot $h(x)$ in $T$.

Given $S \subseteq \mathcal{U}$. How do we store $S$ and how do we do lookups?

## Ideal situation:

(1) Each element $x \in S$ hashes to a distinct slot in $T$. Store $x$ in slot $h(x)$
(2) Lookup: Given $y \in \mathcal{U}$ check if $T[h(y)]=y$. $O(1)$ time!

Collisions unavoidable if $|\boldsymbol{T}|<|\mathcal{U}|$.

## Handling Collisions: Chaining

Collision: $h(x)=h(y)$ for some $x \neq y$.
Chaining/Open hashing to handle collisions:
(1) For each slot $i$ store all items hashed to slot $i$ in a linked list. $T[i]$ points to the linked list
(2) Lookup: to find if $y \in \mathcal{U}$ is in $T$, check the linked list at $T[h(y)]$. Time proportion to size of linked list.

Does hashing give $O(1)$ time per operation for dictionaries?

## Hash Functions

Parameters: $N=|\mathcal{U}|$ (very large), $m=|T|, n=|S|$
Goal: $O(1)$-time lookup, insertion, deletion.

## Single hash function

If $\boldsymbol{N} \geq \boldsymbol{m}^{2}$, then for any hash function $\boldsymbol{h}: \mathcal{U} \rightarrow \boldsymbol{T}$ there exists $\boldsymbol{i}<\boldsymbol{m}$ such that at least $\boldsymbol{N} / \boldsymbol{m} \geq \boldsymbol{m}$ elements of $\mathcal{U}$ get hashed to slot $i$. Any $S$ containing all of these is a very very bad set for $h$ ! Such a bad set may lead to $\boldsymbol{O}(\boldsymbol{m})$ lookup time!

In practice:

- Dictionary applications: choose a simple hash function and hope that worst-case bad sets do not arise
- Crypto applications: create "hard" and "complex" function very carefully which makes finding collisions difficult

## Hashing from a theoretical point of view

- Consider a family $\mathcal{H}$ of hash functions with good properties and choose $\boldsymbol{h}$ randomly from $\mathcal{H}$
- Guarantees: small \# collisions in expectation for any given $S$.
- $\mathcal{H}$ should allow efficient sampling.
- Each $\boldsymbol{h} \in \mathcal{H}$ should be efficient to evaluate and require small memory to store.

In other words a hash function is a "pseudorandom" function

## Strongly Universal Hashing

(1) Uniform: Consider any element $x \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then $x$ should go into a random slot in $T$. In other words $\operatorname{Pr}[h(x)=i]=1 / m$ for every $0 \leq i<m$.
(2) (2)-Strongly Universal: Consider any two distinct elements $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then $\boldsymbol{h}(\boldsymbol{x})$ and $\boldsymbol{h}(\boldsymbol{y})$ should be independent random variables.

## Universal Hashing

- (2)-Universal: Consider any two distinct elements $x, y \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then the probability of a collision between $x$ and $y$ should be at most $\mathbf{1 / m}$. In other words $\operatorname{Pr}[h(x)=h(y)] \leq 1 / m$.
Note: we do not insist on uniformity.

## Universal Hashing

- (2)-Universal: Consider any two distinct elements $x, y \in \mathcal{U}$. Then if $\boldsymbol{h} \in \mathcal{H}$ is picked randomly then the probability of a collision between $x$ and $y$ should be at most $\mathbf{1 / m}$. In other words $\operatorname{Pr}[h(x)=h(y)] \leq 1 / m$.
Note: we do not insist on uniformity.
Universal hashing is a relaxation of strong universal hashing and simpler to construct while retaining most of the useful properties.

## (Strongly) Universal Hashing

## Definition

A family of hash functions $\mathcal{H}$ is (2-)strongly universal if for all distinct $\boldsymbol{x}, \boldsymbol{y} \in \mathcal{U}, \boldsymbol{h}(\boldsymbol{x})$ and $\boldsymbol{h}(\boldsymbol{y})$ are independent for $\boldsymbol{h}$ chosen uniformly at random from $\mathcal{H}$, and for all $\boldsymbol{x}, \boldsymbol{h}(\boldsymbol{x})$ is uniformly distributed.

## Definition

A family of hash functions $\mathcal{H}$ is (2-)universal if for all distinct $x, y \in \mathcal{U}, \operatorname{Pr}_{h \sim \mathcal{H}}[h(x)=h(y)] \leq 1 / m$ where $\boldsymbol{m}$ is the table size.

## Analyzing Universal Hashing

(1) $\boldsymbol{T}$ is hash table of size $\boldsymbol{m}$.
(2) $S \subseteq \mathcal{U}$ is a fixed set of size $n$
(3) $\boldsymbol{h}$ is chosen randomly from a universal hash family $\mathcal{H}$.
(4) $\boldsymbol{x}$ is a fixed element of $\mathcal{U}$.

Question: What is the expected time to look up $x$ in $T$ using $h$ assuming chaining used to resolve collisions?

## Analyzing Universal Hashing

(1) $\boldsymbol{T}$ is hash table of size $\boldsymbol{m}$.
(2) $S \subseteq \mathcal{U}$ is a fixed set of size $n$
(0) $\boldsymbol{h}$ is chosen randomly from a universal hash family $\mathcal{H}$.
(0) $x$ is a fixed element of $\mathcal{U}$.

Question: What is the expected time to look up $x$ in $T$ using $h$ assuming chaining used to resolve collisions?
(1) The time to look up $x$ is the size of the list at $T[h(x)]$ : same as the number of elements in $S$ that collide with $x$ under $h$.
(2) $\ell(x)$ be this number. We want $\mathrm{E}[\ell(x)]$
(0) Let $C_{x, y}$ be indicator random variable for $\boldsymbol{x}, \boldsymbol{y}$ colloding under $h$, that $C_{x, y}=1$ iff $h(x)=h(y)$

## Analyzing Universal Hashing

## Continued...

Number of elements colliding with $x: \ell(x)=\sum_{y \in S} C_{x, y}$.

$$
\begin{aligned}
\Rightarrow \mathrm{E}[\ell(x)] & =\sum_{y \in S, y \neq x} \mathrm{E}\left[C_{x, y}\right] \quad \text { linearity of expectation } \\
& =\sum_{y \in S, y \neq x} \operatorname{Pr}[h(x)=h(y)] \\
& \leq \sum_{y \in S, y \neq x} \frac{1}{m} \quad \text { (since } \mathcal{H} \text { is a universal hash } \\
& \leq|S| / m \\
& \leq \frac{n}{m} \\
& \leq 1 \quad
\end{aligned}
$$

## Analyzing Universal Hashing

Comments:
(1) Expected time for insertion and deletion also $O(1)$ if $n \leq m$.
(2) Analysis assumes static set $S$ but holds as long as $S$ is a set formed with at most $O(\boldsymbol{m})$ insertions and deletions.
Assumption is that insertions and deletions are not adaptive.
(3) Worst-case: look up time can be large! How large? Technically $O(n)$ if all elements collide.

## Analyzing Universal Hashing: Maximum Load

If $\boldsymbol{h}$ is a fully random function and $\boldsymbol{m}=\boldsymbol{n}$ then expected maximum load in any bucket of $T$ is $O(\log n / \log \log n)$ via balls and bin analogy.

If $\boldsymbol{h}$ is chosen from a universal hash family $\mathcal{H}$ what is the expected maximum load?

## Lemma

Let $\boldsymbol{h}$ be chosen from a universal hash family and let $\boldsymbol{m} \geq \boldsymbol{n}$ and let $L$ be maximum load of any slot. Then $\operatorname{Pr}[L>t \sqrt{n}] \leq \mathbf{1} / t^{2}$ for $t \geq 1$.

## Analyzing Universal Hashing: Maximum Load

If $\boldsymbol{h}$ is a fully random function and $\boldsymbol{m}=\boldsymbol{n}$ then expected maximum load in any bucket of $T$ is $O(\log n / \log \log n)$ via balls and bin analogy.

If $\boldsymbol{h}$ is chosen from a universal hash family $\mathcal{H}$ what is the expected maximum load?

## Lemma

Let $\boldsymbol{h}$ be chosen from a universal hash family and let $\boldsymbol{m} \geq \boldsymbol{n}$ and let $L$ be maximum load of any slot. Then $\operatorname{Pr}[L>t \sqrt{n}] \leq \mathbf{1} / t^{2}$ for $t \geq 1$.

Thus $L=O(\sqrt{n})$ with probability at least $\mathbf{1} / \mathbf{2}$.

## Analyzing Universal Hashing: Maximum Load

## Lemma

Let $\boldsymbol{h}$ be chosen from a universal hash family and let $\boldsymbol{m} \geq \boldsymbol{n}$ and let $L$ be maximum load of any slot. Then $\operatorname{Pr}[L>t \sqrt{n}] \leq \mathbf{1} / t^{2}$ for $t \geq 1$.

Let $C=\sum_{x, y \in s, x \neq y} C_{x, y}$ be total number of collisions.

- $\mathrm{E}[C] \leq\binom{ n}{2} / m \leq(n-1) / 2$ if $m \geq n$.
- Observation: $C \geq\binom{ L}{2}$. Why?
- $L>t \sqrt{n}$ implies $C>t^{2} n / 2$.
- By Markov $\operatorname{Pr}\left[C>t^{2} n / 2\right] \leq \mathrm{E}[C] /\left(t^{2} n / 2\right) \leq 1 / t^{2}$
- Hence $\operatorname{Pr}[L>t \sqrt{n}] \leq 1 / t^{2}$.

## Analyzing Universal Hashing: Maximum Load

## Lemma

Let $\boldsymbol{h}$ be chosen from a universal hash family and let $\boldsymbol{m} \geq \boldsymbol{n}$ and let $L$ be maximum load of any slot. Then $\mathrm{E}[L]=O(\sqrt{n})$.

Direct proof: $(\mathrm{E}[L])^{2} \leq \mathrm{E}\left[L^{2}\right] \leq \mathrm{E}[C] \leq \boldsymbol{n}$ (using Jensen's ineq)
$L$ is a non-negative random variable in range. Hence

$$
\begin{aligned}
E[L] & =\sum_{i=1}^{n} \operatorname{Pr}[L \geq i] \quad \text { (from defn of expectation) } \\
& \leq \sum_{i=1}^{\sqrt{n}} 1+\sum_{i=\sqrt{n}+1}^{n} n / i^{2} \quad \text { (from previous lemma) } \\
& \leq \sqrt{n}+n \int_{\sqrt{n}}^{n} 1 / i^{2} \leq 2 \sqrt{n}
\end{aligned}
$$

## Compact Strongly Universal Hash Family

Parameters: $N=|\mathcal{U}|, m=|T|, n=|S|$
Question: How do we construct strongly universal hash family?

## Compact Strongly Universal Hash Family

Parameters: $N=|\mathcal{U}|, m=|T|, n=|S|$
Question: How do we construct strongly universal hash family?
If $N$ and $\boldsymbol{m}$ are powers of $\mathbf{2}$ then use construction of $N$ pairwise independent random variables over range $[m$ ] discussed previously

## Compact Strongly Universal Hash Family

Parameters: $N=|\mathcal{U}|, m=|T|, n=|S|$
Question: How do we construct strongly universal hash family?
If $N$ and $\boldsymbol{m}$ are powers of $\mathbf{2}$ then use construction of $N$ pairwise independent random variables over range [ $m$ ] discussed previously

Disadvantage: Need $\boldsymbol{m}$ to be power of $\mathbf{2}$ and requires complicated field operations

## Compact Universal Hash Family

Parameters: $N=|\mathcal{U}|, m=|T|, n=|S|$
(1) Choose a prime number $p>N$. Define function $h_{a, b}(x)=((a x+b) \bmod p) \bmod m$.
(2) Let $\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{p}, a \neq 0\right\}\left(\mathbb{Z}_{p}=\{0,1, \ldots, p-1\}\right)$. Note that $|\mathcal{H}|=p(p-1)$.

## Compact Universal Hash Family

Parameters: $N=|\mathcal{U}|, m=|T|, n=|S|$
(1) Choose a prime number $p>N$. Define function $h_{a, b}(x)=((a x+b) \bmod p) \bmod m$.
(2) Let $\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{p}, a \neq 0\right\}\left(\mathbb{Z}_{p}=\{0,1, \ldots, p-1\}\right)$. Note that $|\mathcal{H}|=p(p-1)$.

## Theorem

$\mathcal{H}$ is a universal hash family.

## Compact Universal Hash Family

Parameters: $N=|\mathcal{U}|, m=|T|, n=|S|$
(1) Choose a prime number $p>N$. Define function $h_{a, b}(x)=((a x+b) \bmod p) \bmod m$.
(2) Let $\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{p}, a \neq 0\right\}\left(\mathbb{Z}_{p}=\{0,1, \ldots, p-1\}\right)$. Note that $|\mathcal{H}|=p(p-1)$.

## Theorem

## $\mathcal{H}$ is a universal hash family.

Comments:
(1) $h_{a, b}$ can be evaluated in $O(\mathbf{1})$ time.
(2) Easy to store, i.e., just store a, b. Easy to sample.

## Understanding the hashing

Once we fix $\boldsymbol{a}$ and $\boldsymbol{b}$, and we are given a value $\boldsymbol{x}$, we compute the hash value of $x$ in two stages:
(1) Compute: $r \leftarrow(a x+b) \bmod p$.
(2) Fold: $r^{\prime} \leftarrow r \bmod m$

Let $g_{a, b}(x)=(a x+b) \bmod p$.
$h_{a, b}(x)=g_{a, b}(x) \bmod m$.

## Understanding the hashing

Once we fix $\boldsymbol{a}$ and $\boldsymbol{b}$, and we are given a value $\boldsymbol{x}$, we compute the hash value of $x$ in two stages:
(1) Compute: $r \leftarrow(a x+b) \bmod p$.
(2) Fold: $r^{\prime} \leftarrow r \bmod m$

Let $g_{a, b}(x)=(a x+b) \bmod p$.
$h_{a, b}(x)=g_{a, b}(x) \bmod m$.
Fix $x$ :

- $\boldsymbol{g}_{\mathrm{a}, \boldsymbol{b}}(x)$ is uniformly distributed in $\{\mathbf{0}, \mathbf{1}, \ldots, \boldsymbol{p}-\mathbf{1}\}$. Why?
- However $\boldsymbol{h}_{\mathbf{a}, \boldsymbol{b}}(\boldsymbol{x})$ is not necessarily uniformly distributed over $\{0,1,2, \ldots, m\}$. Why?

## Some math required...

Recall $\mathbb{Z}_{\boldsymbol{p}}$ is a field.

- $a \neq 0$ implies unique $a^{\prime}$ such that $a a^{\prime}=\mathbf{1} \bmod p$
- For $a, x, y \in \mathbb{Z}_{p}$ such that $x \neq y$ and $a \neq 0$ we have $a x \neq a y \bmod p$.
- For $x \neq y$ and any $r, s$ there is a unique solution $(a, b)$ to the equations $a x+b=r$ and $a y+b=s$.

## Proof of the Theorem: Outline

$\left.h_{a, b}(x)=((a x+b) \bmod p) \bmod m\right)$.
Theorem
$\mathcal{H}=\left\{\boldsymbol{h}_{a, b} \mid a, b \in \mathbb{Z}_{\boldsymbol{p}}, \boldsymbol{a} \neq 0\right\}$ is universal.

## Proof.

Fix $x, y \in \mathcal{U}, x \neq y$. Show that $\operatorname{Pr}_{h_{a}, b} \sim \mathcal{H}\left[h_{a, b}(x)=h_{a, b}(y)\right] \leq 1 / m$.
Note that $|\mathcal{H}|=p(p-1)$.

## Proof of the Theorem: Outline

$$
\left.h_{a, b}(x)=((a x+b) \bmod p) \bmod m\right) .
$$

## Theorem

$\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{\boldsymbol{p}}, a \neq 0\right\}$ is universal.

## Proof.

Fix $x, y \in \mathcal{U}, x \neq y$. Show that
$\operatorname{Pr}_{h_{a, b} \sim \mathcal{H}}\left[h_{a, b}(x)=h_{a, b}(y)\right] \leq 1 / m$.
Note that $|\mathcal{H}|=p(p-1)$.
(1) Let $(\boldsymbol{a}, \boldsymbol{b})$ (equivalently $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}$ ) be bad for $\boldsymbol{x}, \boldsymbol{y}$ if $h_{a, b}(x)=h_{a, b}(y)$.

## Proof of the Theorem: Outline

$$
\left.h_{a, b}(x)=((a x+b) \bmod p) \bmod m\right) .
$$

## Theorem

$\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{\boldsymbol{p}}, a \neq 0\right\}$ is universal.

## Proof.

Fix $x, y \in \mathcal{U}, x \neq y$. Show that
$\operatorname{Pr}_{\boldsymbol{h}_{\mathrm{a}, \boldsymbol{b}} \sim \mathcal{H}}\left[\boldsymbol{h}_{\mathrm{a}, \boldsymbol{b}}(\boldsymbol{x})=\boldsymbol{h}_{\mathrm{a}, \boldsymbol{b}}(\boldsymbol{y})\right] \leq \mathbf{1} / \boldsymbol{m}$.
Note that $|\mathcal{H}|=p(p-1)$.
(1) Let $(\boldsymbol{a}, \boldsymbol{b})$ (equivalently $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}$ ) be bad for $\boldsymbol{x}, \boldsymbol{y}$ if $h_{a, b}(x)=h_{a, b}(y)$.
(2) Claim: Number of bad $(a, b)$ is at most $p(p-1) / m$.

## Proof of the Theorem: Outline

$$
\left.h_{a, b}(x)=((a x+b) \bmod p) \bmod m\right) .
$$

## Theorem

$\mathcal{H}=\left\{h_{a, b} \mid a, b \in \mathbb{Z}_{\boldsymbol{p}}, a \neq 0\right\}$ is universal.

## Proof.

Fix $x, y \in \mathcal{U}, x \neq y$. Show that
$\operatorname{Pr}_{\boldsymbol{h}_{a, b} \sim \mathcal{H}}\left[\boldsymbol{h}_{\mathrm{a}, \boldsymbol{b}}(\boldsymbol{x})=\boldsymbol{h}_{\mathrm{a}, \boldsymbol{b}}(\boldsymbol{y})\right] \leq \mathbf{1} / \boldsymbol{m}$.
Note that $|\mathcal{H}|=p(p-1)$.
(1) Let $(\boldsymbol{a}, \boldsymbol{b})$ (equivalently $\boldsymbol{h}_{\boldsymbol{a}, \boldsymbol{b}}$ ) be bad for $\boldsymbol{x}, \boldsymbol{y}$ if $h_{a, b}(x)=h_{a, b}(y)$.
(2) Claim: Number of bad $(a, b)$ is at most $p(p-1) / m$.
(3) Total number of hash functions is $p(p-1)$ and hence probability of a collision is $\leq \mathbf{1 / m}$.

## Proof of Claim

$$
h_{a, b}(x)=(((a x+b) \bmod p) \bmod m)
$$

2 lemmas ...

Fix $x \neq y \in \mathbb{Z}_{p}$, and let $r=(a x+b) \bmod p$ and $s=(a y+b) \bmod p$.

## Proof of Claim

$$
h_{a, b}(x)=(((a x+b) \bmod p) \bmod m)
$$

2 lemmas ...
Fix $x \neq y \in \mathbb{Z}_{p}$, and let $r=(a x+b) \bmod p$ and $s=(a y+b) \bmod p$.
(1) 1-to-1 correspondence between $p(p-1)$ pairs of $(a, b)$ (equivalently $h_{a, b}$ ) and $p(p-1)$ pairs of $(r, s)$.

## Proof of Claim

$$
h_{a, b}(x)=(((a x+b) \bmod p) \bmod m)
$$

2 lemmas ...

Fix $x \neq y \in \mathbb{Z}_{p}$, and let $r=(a x+b) \bmod p$ and $s=(a y+b) \bmod p$.
(1) 1-to-1 correspondence between $p(p-1)$ pairs of $(a, b)$ (equivalently $h_{a, b}$ ) and $p(p-1)$ pairs of $(r, s)$.
(2) Out of all possible $p(p-1)$ pairs of $(r, s)$, at most $p(p-1) / m$ fraction satisfies $r \bmod m=s \bmod m$.

## Correspondence Lemma

## Lemma

If $x \neq y$ then for each $(r, s)$ such that $r \neq s$ and
$\mathbf{0} \leq r, s \leq p-1$ there is exactly one pair $(a, b)$ such that $a \neq 0$ and $a x+b \bmod p=r$ and $a y+b \bmod p=s$

## Proof.

Solve the two equations:

$$
a x+b=r \quad \bmod p \quad \text { and } \quad a y+b=s \quad \bmod p
$$

We get $a=\frac{r-s}{x-y} \bmod p$ and $b=r-a x \bmod p$.
One-to-one correspondence between $(a, b)$ and $(r, s)$

## Collisions due to folding

Once we fix $\boldsymbol{a}$ and $\boldsymbol{b}$, and we are given a value $\boldsymbol{x}$, we compute the hash value of $x$ in two stages:
(1) Compute: $r \leftarrow(a x+b) \bmod p$.
(2) Fold: $r^{\prime} \leftarrow r \bmod m$

## Collision...

Given two distinct values $x$ and $y$ they might collide only because of folding.

## Collisions due to folding

Once we fix $\boldsymbol{a}$ and $\boldsymbol{b}$, and we are given a value $\boldsymbol{x}$, we compute the hash value of $x$ in two stages:
(1) Compute: $r \leftarrow(a x+b) \bmod p$.
(2) Fold: $r^{\prime} \leftarrow r \bmod m$

## Collision...

Given two distinct values $x$ and $y$ they might collide only because of folding.

## Lemma

\# of pairs $(r, s)$ of $\mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ such that $r \neq s$ and $r \bmod m=s$ $\bmod m$ is at most $p(p-1) / m$.

## Folding numbers

## Lemma

$\#$ pairs $(r, s) \in \mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ such that $r \neq s$ and $r \bmod m=s$ $\bmod m$ (folded to the same number) is $p(p-1) / m$.

## Proof.

Consider a pair $(r, s) \in\{0,1, \ldots, p-1\}^{2}$ s.t. $r \neq s$. Fix $r$ :
(1) Let $d=r \bmod m$.

## Folding numbers

## Lemma

$\#$ pairs $(r, s) \in \mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ such that $r \neq s$ and $r \bmod m=s$ $\bmod m$ (folded to the same number) is $p(p-1) / m$.

## Proof.

Consider a pair $(r, s) \in\{0,1, \ldots, p-1\}^{2}$ s.t. $r \neq s$. Fix $r$ :
(1) Let $d=r \bmod \boldsymbol{m}$.
(2) There are $\lceil p / m\rceil$ values of $s$ such that $r \bmod m=s$ $\bmod \boldsymbol{m}$.
(3) One of them is when $r=s$.
( 3$) \#$ of colliding pairs

## Folding numbers

## Lemma

$\#$ pairs $(r, s) \in \mathbb{Z}_{\boldsymbol{p}} \times \mathbb{Z}_{\boldsymbol{p}}$ such that $r \neq s$ and $r \bmod m=s$ $\bmod m$ (folded to the same number) is $p(p-1) / m$.

## Proof.

Consider a pair $(r, s) \in\{0,1, \ldots, p-1\}^{2}$ s.t. $r \neq s$. Fix $r$ :
(1) Let $d=r \bmod \boldsymbol{m}$.
(2) There are $\lceil p / m\rceil$ values of $s$ such that $r \bmod m=s$ $\bmod m$.
(3) One of them is when $r=s$.
(9) $\Longrightarrow \#$ of colliding pairs $(\lceil p / m\rceil-1) p \leq(p-1) p / m$

## Proof of Claim

 \# of bad pairs is $p(p-1) / m$
## Proof.

Let $a, b \in \mathbb{Z}_{\boldsymbol{p}}$ such that $\boldsymbol{a} \neq 0$ and $\boldsymbol{h}_{a, b}(x)=h_{a, b}(y)$.
(1) Let $r=a x+b \bmod p$ and $s=a y+b \bmod p$.
(2) Collision if and only if $r \bmod m=s \bmod m$.
(3) (Folding error): Number of pairs $(r, s)$ such that $r \neq s$ and $0 \leq r, s \leq p-1$ and $r \bmod m=s \bmod m$ is $p(p-1) / m$.
(4) From previous lemma there is one-to-one correspondence between $(\boldsymbol{a}, \boldsymbol{b})$ and $(\boldsymbol{r}, \boldsymbol{s})$. Hence total number of bad $(\boldsymbol{a}, \boldsymbol{b})$ pairs is $p(p-1) / m$.

## Proof of Claim

 \# of bad pairs is $p(p-1) / m$
## Proof.

Let $a, b \in \mathbb{Z}_{\boldsymbol{p}}$ such that $\boldsymbol{a} \neq 0$ and $\boldsymbol{h}_{a, b}(x)=h_{a, b}(y)$.
(1) Let $r=a x+b \bmod p$ and $s=a y+b \bmod p$.
(2) Collision if and only if $r \bmod m=s \bmod m$.
(3) (Folding error): Number of pairs $(r, s)$ such that $r \neq s$ and $0 \leq r, s \leq p-1$ and $r \bmod m=s \bmod m$ is $p(p-1) / m$.
(4) From previous lemma there is one-to-one correspondence between $(\boldsymbol{a}, \boldsymbol{b})$ and $(\boldsymbol{r}, \boldsymbol{s})$. Hence total number of bad $(\boldsymbol{a}, \boldsymbol{b})$ pairs is $p(p-1) / m$.

Prob of $x$ and $y$ to collide: $\frac{\# \text { bad }(a, b) \text { pairs }}{\#(a, b) \text { pairs }}=\frac{\boldsymbol{p}(\boldsymbol{p}-1) / \boldsymbol{m}}{\boldsymbol{p}(\boldsymbol{p}-\mathbf{1})}=\frac{\mathbf{1}}{\boldsymbol{m}}$.

## Part III

## Perfect Hashing

## Perfect Hashing

Question: Suppose we get a set $\boldsymbol{S} \subset \mathcal{U}$ of size $\boldsymbol{n}$. Can we design an "efficient" and "perfect" hash function?

- Create a table $T$ of size $m=O(n)$.
- Create a hash function $h: S \rightarrow[m]$ with no collisions!
- $\boldsymbol{h}$ should be fast and efficient to evaluate
- Construct $\boldsymbol{h}$ efficiently given $\boldsymbol{S}$. Construction of $\boldsymbol{h}$ can be randomized (Las Vegas algorithm)

## Perfect Hashing

Question: Suppose we get a set $\boldsymbol{S} \subset \mathcal{U}$ of size $\boldsymbol{n}$. Can we design an "efficient" and "perfect" hash function?

- Create a table $T$ of size $m=O(n)$.
- Create a hash function $h: S \rightarrow[m]$ with no collisions!
- $\boldsymbol{h}$ should be fast and efficient to evaluate
- Construct $\boldsymbol{h}$ efficiently given $\boldsymbol{S}$. Construction of $\boldsymbol{h}$ can be randomized (Las Vegas algorithm)

A perfect hash function would guarantee lookup time of $O(1)$.

## Perfect Hashing via Large Space

Suppose $\boldsymbol{m}=\boldsymbol{n}^{2}$. Table size is much bigger than $\boldsymbol{n}$

## Lemma

Suppose $\mathcal{H}$ is a universal hash family and $m=\boldsymbol{n}^{2}$. Then $\operatorname{Pr}_{\boldsymbol{h} \in \mathcal{H}}[$ no collisions in $S] \geq \mathbf{1 / 2}$.

## Perfect Hashing via Large Space

Suppose $\boldsymbol{m}=\boldsymbol{n}^{2}$. Table size is much bigger than $\boldsymbol{n}$

## Lemma

Suppose $\mathcal{H}$ is a universal hash family and $m=\boldsymbol{n}^{2}$. Then $\operatorname{Pr}_{\boldsymbol{h} \in \mathcal{H}}[$ no collisions in $S] \geq \mathbf{1 / 2}$.

## Proof.

- Total number of collisions is $C=\sum_{x, y \in S, x \neq y} C_{x, y}$.
- $\mathrm{E}[C] \leq\binom{ n}{2} / \boldsymbol{m}<\mathbf{1} / \mathbf{2}$.
- By Markov inequality $\operatorname{Pr}[C \geq 1]<1 / 2$.

## Perfect Hashing via Large Space

Suppose $\boldsymbol{m}=\boldsymbol{n}^{2}$. Table size is much bigger than $\boldsymbol{n}$

## Lemma

Suppose $\mathcal{H}$ is a universal hash family and $m=\boldsymbol{n}^{2}$. Then $\operatorname{Pr}_{h \in \mathcal{H}}[$ no collisions in $S] \geq \mathbf{1 / 2}$.

## Proof.

- Total number of collisions is $C=\sum_{x, y \in S, x \neq y} C_{x, y}$.
- $\mathrm{E}[C] \leq\binom{ n}{2} / \boldsymbol{m}<\mathbf{1} / \mathbf{2}$.
- By Markov inequality $\operatorname{Pr}[C \geq 1]<1 / 2$.

Algorithm: pick $\boldsymbol{h} \in \mathcal{H}$ randomly and check if $\boldsymbol{h}$ is perfect. Repeat until success.

## Perfect Hashing

## Two levels of hash tables

Question: Can we obtain perfect hashing with $m=O(n)$ ?

## Perfect Hashing

- Do hashing once with table $\boldsymbol{T}$ of size $\boldsymbol{m}$
- For each slot $i$ in $T$ let $Y_{i}$ be number of elements hashed to slot $\boldsymbol{i}$. If $\boldsymbol{Y}_{\boldsymbol{i}}>\mathbf{1}$ use perfect hashing with second table $\boldsymbol{T}_{\boldsymbol{i}}$ of size $Y_{i}^{2}$.

## Perfect Hashing

## Two levels of hash tables

Question: Can we obtain perfect hashing with $m=O(n)$ ?

## Perfect Hashing

- Do hashing once with table $\boldsymbol{T}$ of size $\boldsymbol{m}$
- For each slot $i$ in $T$ let $Y_{i}$ be number of elements hashed to slot $i$. If $Y_{i}>\mathbf{1}$ use perfect hashing with second table $\boldsymbol{T}_{\boldsymbol{i}}$ of size $Y_{i}^{2}$.

Construction gives perfect hashing. What is the space used?

## Perfect Hashing

## Two levels of hash tables

Question: Can we obtain perfect hashing with $m=O(n)$ ?

## Perfect Hashing

- Do hashing once with table $\boldsymbol{T}$ of size $\boldsymbol{m}$
- For each slot $i$ in $T$ let $Y_{i}$ be number of elements hashed to slot $\boldsymbol{i}$. If $\boldsymbol{Y}_{\boldsymbol{i}}>\mathbf{1}$ use perfect hashing with second table $\boldsymbol{T}_{\boldsymbol{i}}$ of size $Y_{i}^{2}$.

Construction gives perfect hashing. What is the space used?

$$
Z=m+\sum_{i=0}^{m-1} Y_{i}^{2}
$$

a random variable (depends on random choice of first level hash function)

## Perfect Hashing

 $\mathrm{O}(\mathrm{n})$ space usage$\boldsymbol{h}$ the primary random hash function.

## Perfect Hashing $\mathrm{O}(\mathrm{n})$ space usage

$\boldsymbol{h}$ the primary random hash function.

## Claim

$E\left[\sum_{i=0}^{m-1} Y_{i}^{2}\right] \leq 3 n / 2$ if $m \geq n$.

## Perfect Hashing

 $\mathrm{O}(\mathrm{n})$ space usage$\boldsymbol{h}$ the primary random hash function.

## Claim

$$
E\left[\sum_{i=0}^{m-1} Y_{i}^{2}\right] \leq 3 n / 2 \text { if } m \geq n
$$

## Proof.

Let $\boldsymbol{C}$ be total number of collisions. We already saw $\mathbf{E}[\boldsymbol{C}] \leq\binom{\boldsymbol{n}}{2} / \boldsymbol{m}$.

## Perfect Hashing

## $\mathrm{O}(\mathrm{n})$ space usage

$\boldsymbol{h}$ the primary random hash function.

## Claim

$$
E\left[\sum_{i=0}^{m-1} Y_{i}^{2}\right] \leq 3 n / 2 \text { if } m \geq n
$$

## Proof.

Let $C$ be total number of collisions. We already saw $\mathrm{E}[\boldsymbol{C}] \leq\binom{\boldsymbol{n}}{2} / \boldsymbol{m}$. $\sum_{i}\binom{\boldsymbol{Y}_{i}}{2}=\boldsymbol{C}$ and hence $\sum_{i} \boldsymbol{Y}_{i}^{2}=\mathbf{C}+\sum_{i} \boldsymbol{Y}_{\boldsymbol{i}}$.
Therefore

$$
\mathrm{E}\left[\sum_{i} Y_{i}^{2}\right] \leq 2\binom{n}{2} / m+E\left[\sum_{i} Y_{i}\right]=2\binom{n}{2} / m+n \leq 3 n / 2
$$

## Perfect Hashing

## Perfect Hashing

- Do hashing once with table $T$ of size $\boldsymbol{m}$
- For each slot $\boldsymbol{i}$ in $\boldsymbol{T}$ let $Y_{i}$ be number of elements hashed to slot $\boldsymbol{i}$. If $\boldsymbol{Y}_{\boldsymbol{i}}>\mathbf{1}$ use perfect hashing with second table $\boldsymbol{T}_{\boldsymbol{i}}$ of size $Y_{i}^{2}$.

Space usage is $Z=m+\sum_{i=0}^{m-1} Y_{i}^{2}$ and $\mathrm{E}[Z] \leq 5 n / 2$ if $m=n$.

- Use algorithm to create perfect hash table
- By Markov space usage is $<\mathbf{5 n}$ with probability at least $\mathbf{1 / 2}$
- Repeat if space usage is larger than 5 n. Expected number of repetitions is 2 . Hence it leads to $\boldsymbol{O}(\boldsymbol{n})$ time Las Vegas algorithm
- Technically also need to count the space to store multiple hash functions: $O(n)$ overhead

## Rehashing, amortization and...

making the hash table dynamic
So far we assumed fixed $S$ of size $\simeq \boldsymbol{m}$.
Question: What happens as items are inserted and deleted?
(1) If $|S|$ grows to more than $\mathbf{c m}$ for some constant $c$ then hash table performance clearly degrades.
(2) If $|S|$ stays around $\simeq \boldsymbol{m}$ but incurs many insertions and deletions then the initial random hash function is no longer random enough!

## Rehashing, amortization and...

making the hash table dynamic
So far we assumed fixed $S$ of size $\simeq \boldsymbol{m}$.
Question: What happens as items are inserted and deleted?
(1) If $|S|$ grows to more than $\mathbf{c m}$ for some constant $c$ then hash table performance clearly degrades.
(2) If $|\boldsymbol{S}|$ stays around $\simeq \boldsymbol{m}$ but incurs many insertions and deletions then the initial random hash function is no longer random enough!
Solution: Rebuild hash table periodically!
(1) Choose a new table size based on current number of elements in the table.
(2) Choose a new random hash function and rehash the elements.
(3) Discard old table and hash function.

Question: When to rebuild? How expensive?

## Rebuilding the hash table

(1) Start with table size $\boldsymbol{m}$ where $\boldsymbol{m}$ is some estimate of $|S|$ (can be some large constant).
(2) If $|S|$ grows to more than twice current table size, build new hash table (choose a new random hash function) with double the current number of elements. Can also use similar trick if table size falls below quarter the size.

## Rebuilding the hash table

(1) Start with table size $\boldsymbol{m}$ where $\boldsymbol{m}$ is some estimate of $|S|$ (can be some large constant).
(2) If $|S|$ grows to more than twice current table size, build new hash table (choose a new random hash function) with double the current number of elements. Can also use similar trick if table size falls below quarter the size.
(3) If $|S|$ stays roughly the same but more than $c|S|$ operations on table for some chosen constant c (say 10), rebuild.

## Rebuilding the hash table

(1) Start with table size $\boldsymbol{m}$ where $\boldsymbol{m}$ is some estimate of $|\boldsymbol{S}|$ (can be some large constant).
(2) If $|S|$ grows to more than twice current table size, build new hash table (choose a new random hash function) with double the current number of elements. Can also use similar trick if table size falls below quarter the size.
(3) If $|S|$ stays roughly the same but more than $c|S|$ operations on table for some chosen constant $c$ (say 10), rebuild.

The amortize cost of rebuilding to previously performed operations. Rebuilding ensures $O(\mathbf{1})$ expected analysis holds even when $S$ changes. Hence $O(\mathbf{1})$ expected look up/insert/delete time dynamic data dictionary data structure!

## Practical Issues

Hashing used typically for integers, vectors, strings etc.

- Universal hashing is defined for integers. To implement for other objects need to map objects in some fashion to integers (via representation)
- Practical methods for various important cases such as vectors, strings are studied extensively. See http://en.wikipedia.org/wiki/Universal_hashing for some pointers.
- Details on Cuckoo hashing and its advantage over chaining http://en.wikipedia.org/wiki/Cuckoo_hashing.
- Relatively recent important paper bridging theory and practice of hashing. "The power of simple tabulation hashing" by Mikkel Thorup and Mihai Patrascu, 2011. See http://en.wikipedia.org/wiki/Tabulation_hashing

## Part IV

## Bloom Filters

## Bloom Filters

## Hashing:

(1) To insert $x$ in dictionary store $x$ in table in location $h(x)$
(2) To lookup $\boldsymbol{y}$ in dictionary check contents of location $\boldsymbol{h}(\boldsymbol{y})$
(3) Storing items in dictionary expensive in terms of memory, especially if items are unwieldy objects such a long strings, images, etc with non-uniform sizes.

## Bloom Filters

## Hashing:

(1) To insert $x$ in dictionary store $x$ in table in location $h(x)$
(2) To lookup $\boldsymbol{y}$ in dictionary check contents of location $h(y)$
(3) Storing items in dictionary expensive in terms of memory, especially if items are unwieldy objects such a long strings, images, etc with non-uniform sizes.

Bloom Filter: tradeoff space for false positives
(1) To insert $x$ in dictionary set bit to $\mathbf{1}$ in location $\boldsymbol{h ( x )}$ (initially all bits are set to $\mathbf{0}$ )
(2) To lookup $\boldsymbol{y}$ if bit in location $h(y)$ is $\mathbf{1}$ say yes, else no.

## Bloom Filters

Bloom Filter: tradeoff space for false positives
(1) To insert $x$ in dictionary set bit to $\mathbf{1}$ in location $h(x)$ (initially all bits are set to $\mathbf{0}$ )
(2) To lookup $\boldsymbol{y}$ if bit in location $\boldsymbol{h}(\boldsymbol{y})$ is $\mathbf{1}$ say yes, else no
(0) No false negatives but false positives possible due to collisions

## Bloom Filters

Bloom Filter: tradeoff space for false positives
(1) To insert $x$ in dictionary set bit to $\mathbf{1}$ in location $h(x)$ (initially all bits are set to $\mathbf{0}$ )
(2) To lookup $\boldsymbol{y}$ if bit in location $\boldsymbol{h}(\boldsymbol{y})$ is $\mathbf{1}$ say yes, else no
(3) No false negatives but false positives possible due to collisions

Reducing false positives:
(1) Pick $k$ hash functions $h_{1}, h_{2}, \ldots, h_{k}$ independently

## Bloom Filters

Bloom Filter: tradeoff space for false positives
(1) To insert $x$ in dictionary set bit to $\mathbf{1}$ in location $h(x)$ (initially all bits are set to $\mathbf{0}$ )
(2) To lookup $\boldsymbol{y}$ if bit in location $\boldsymbol{h}(\boldsymbol{y})$ is $\mathbf{1}$ say yes, else no

- No false negatives but false positives possible due to collisions

Reducing false positives:
(1) Pick $k$ hash functions $h_{1}, h_{2}, \ldots, h_{k}$ independently
(2) To insert set $\boldsymbol{h}_{\boldsymbol{i}}(x)$ th bit to one in table $\boldsymbol{i}$ for each $\mathbf{1} \leq \boldsymbol{i} \leq \boldsymbol{k}$

## Bloom Filters

Bloom Filter: tradeoff space for false positives
(1) To insert $x$ in dictionary set bit to $\mathbf{1}$ in location $h(x)$ (initially all bits are set to $\mathbf{0}$ )
(2) To lookup $\boldsymbol{y}$ if bit in location $\boldsymbol{h}(\boldsymbol{y})$ is $\mathbf{1}$ say yes, else no
(3) No false negatives but false positives possible due to collisions

Reducing false positives:
(1) Pick $k$ hash functions $h_{1}, h_{2}, \ldots, h_{k}$ independently
(2) To insert set $\boldsymbol{h}_{\boldsymbol{i}}(x)$ th bit to one in table $\boldsymbol{i}$ for each $\mathbf{1} \leq \boldsymbol{i} \leq \boldsymbol{k}$
( To lookup $\boldsymbol{y}$ compute $\boldsymbol{h}_{i}(\boldsymbol{y})$ for $\mathbf{1} \leq \boldsymbol{i} \leq \boldsymbol{k}$ and say yes only if each bit in the corresponding location is $\mathbf{1}$, otherwise say no. If probability of false positive for one hash function is $\alpha<\mathbf{1}$ then with $\boldsymbol{k}$ independent hash function it is $\boldsymbol{\alpha}^{\boldsymbol{k}}$.
