

CS 498wn: Wireless Networking

MAC Layer – Power!

Energy Conservation Techniques

- ▶ Wi-Fi devices consume significant amounts of energy when idle
 - ▶ Idle  1W
- ▶ Conservation Approach: Device suspension (sleep)
 - ▶ Reduced energy consumption
 - ▶ Sleep  0.05W
 - ▶ Suspended communication capabilities
 - ▶ Buffer overflow
 - ▶ Wasted bandwidth
 - ▶ Lost messages
 - ▶ If all nodes are asleep, no one can communicate!

Communication Device Suspension

▶ Goal

- ▶ Adapt the sleep duration to reflect the communication patterns of the application
- ▶ Remain awake when there is active communication
- ▶ Otherwise, suspend

▶ Ideal

- ▶ Sleep whenever there is no data to receive from the base station
- ▶ Wake up for any incoming receptions

Communication Device Suspension

► Problems

- How can a sender differentiate between a suspended node and a node that has gone away?
 - Suspended receiver \Rightarrow buffer packet
 - Confused sender \Rightarrow dropped packet, extra energy consumption
- How can a suspended node know there is communication for it?
 - Wake up too soon \Rightarrow waste energy
 - Wake up too late \Rightarrow delay/miss packets

Communication Device Suspension

- ▶ **Approach**

- ▶ Ensure overlap between sender's and receiver's awake times

- ▶ **Protocols**

- ▶ Triggered Resume
 - ▶ Periodic Resume
 - ▶ Synchronous
 - ▶ Asynchronous

Triggered Resume

▶ Approach

- ▶ Use a second control channel (second radio)
 - ▶ Sender transmits RTS or beacon messages in control channel
 - ▶ Receiver replies in control channel and turns on main channel
- ▶ Main channel is only used for data
- ▶ Second channel
 - ▶ Must consume less energy than the main channel
 - ▶ Must not interfere with the main channel
 - ▶ Ex: RFID, 915Mhz

Triggered Resume

▶ Protocols

▶ Power Aware Multi-Access Protocol (PAMAS)

- ▶ Shut off device when channel is busy

▶ Wake-on-Wireless

- ▶ Control channel is always active

▶ STEM

- ▶ Control channel is managed similar to IEEE 802.11 PSM

Triggered Resume

► Approach – PAMAS

► Data channel

- Power off radio when data is destined to a different node

► Control channel

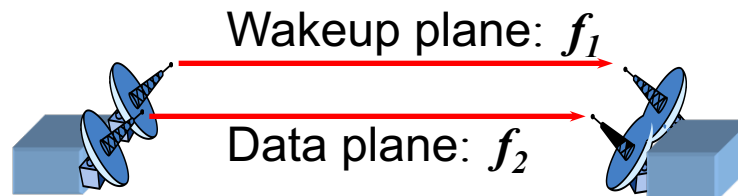

- Probe neighbors to find longest remaining transfer

Triggered Resume

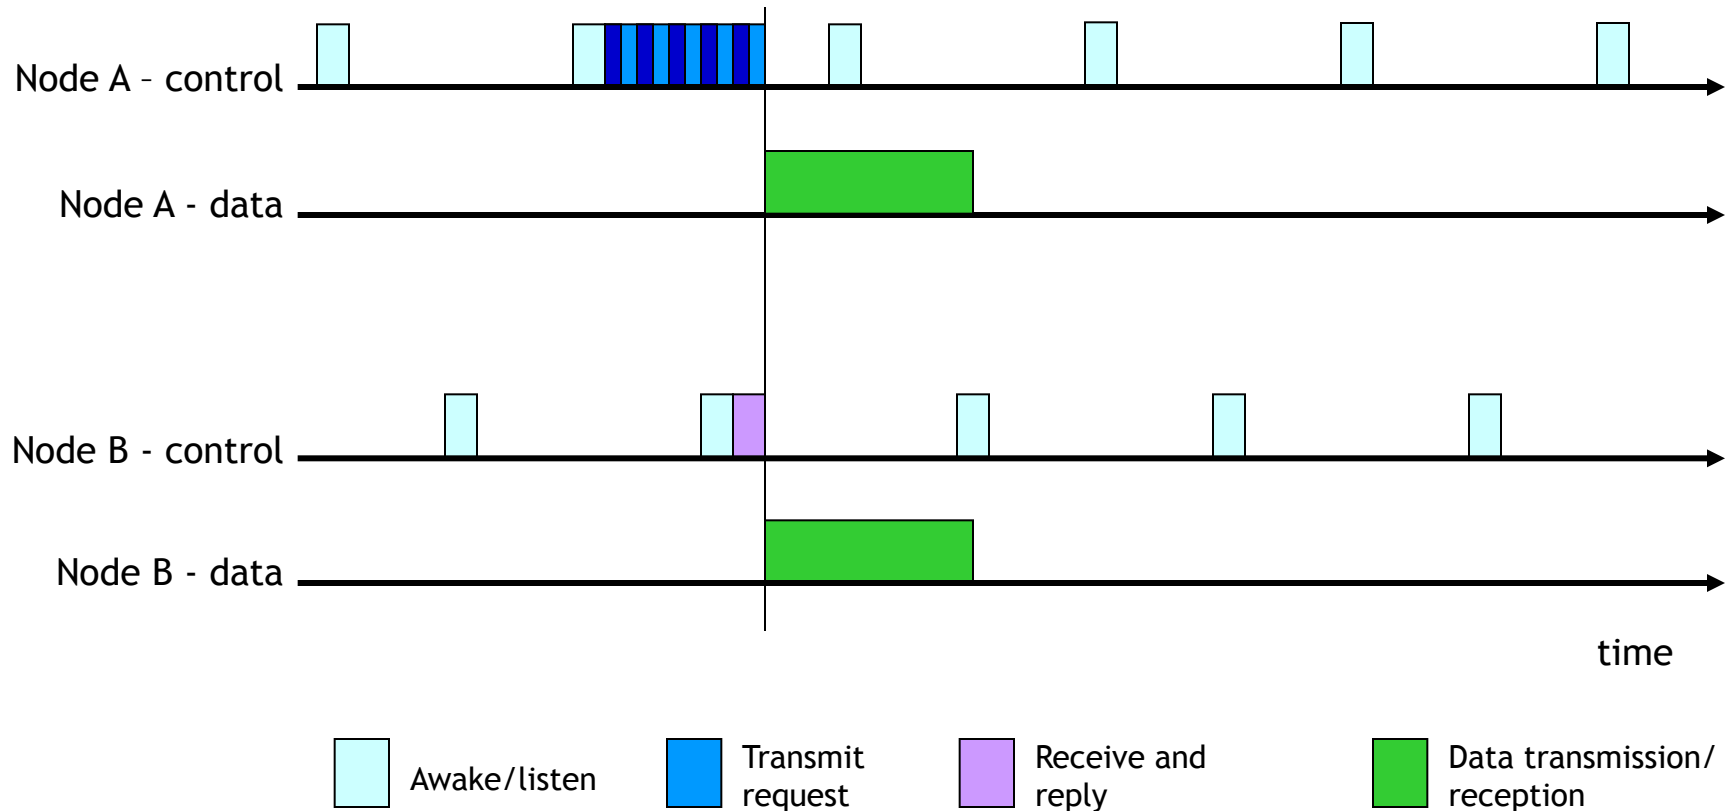

► Dual radio

- Low duty cycle paging channel to wake up a neighboring node
- Use separate radio for the paging channel to avoid interference with regular data forwarding
- Trades off energy savings for setup latency

Triggered Resume

► Dual radio

Triggered Resume

▶ Challenges

- ▶ Two radios are more complex than one
- ▶ Channel characteristics may not be the same for both radios
 - ▶ A successful RTS on the control channel does not guarantee a the reverse channel works
 - ▶ A failed RTS on the control channel does not indicate that the reverse channel does not work

Periodic Resume

▶ Approach

- ▶ Suspend most of the time
- ▶ Periodically resume to check for pending communication

▶ Communication indications

- ▶ Out-of-band channel
- ▶ In-band signaling

▶ Protocols

- ▶ Synchronous
- ▶ Asynchronous

Synchronous Periodic Resume

► Basic Idea

- Time is slotted
- Nodes selectively remain awake for full slot duration
- Discovery occurs when two active slots overlap
- If all nodes are synchronized, all nodes are guaranteed to have overlapping awake periods

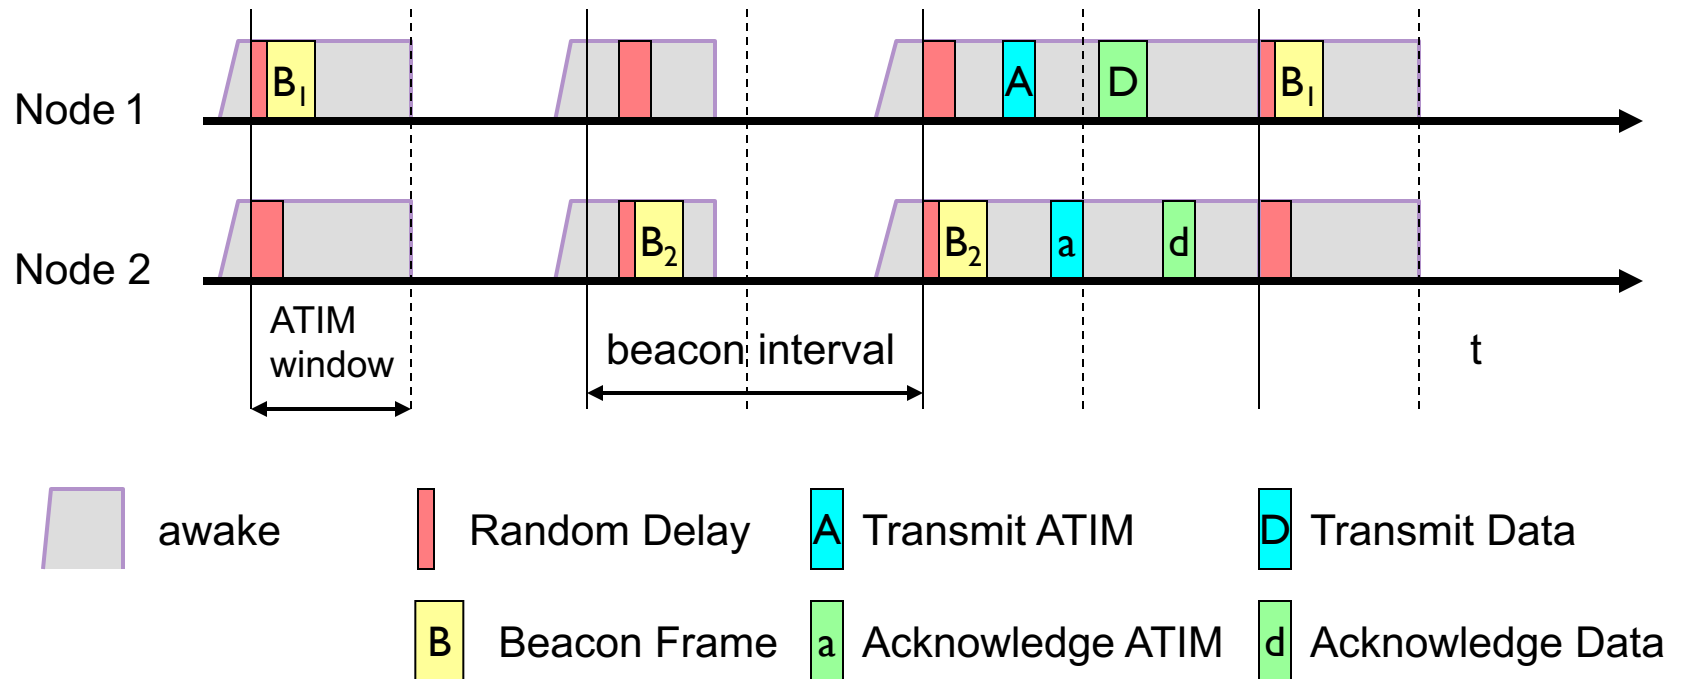

Synchronous Periodic Resume

- ▶ **Protocol: IEEE 802.11 Power Save Mode (PSM)**
 - ▶ Nodes are synchronized and wakeup periodically (Beacon Period)
 - ▶ Each beacon period is broken up into two segments
 - ▶ Ad-hoc Traffic Indication Map (ATIM) Window
 - Announcement in the ATIM indicates data
 - Target node responds with an ATIM ACK
 - If a node receives no announcements, it goes back to sleep
 - ▶ Transmission period
 - Sender can transmit packet until the end of the beacon period

Synchronous Periodic Resume

► IEEE 802.11 PSM

Synchronous Periodic Resume

- ▶ **Centralized solution**

- ▶ Synchronization driven by base station
- ▶ In beacon message

- ▶ **Distributed solution**

- ▶ No base station
- ▶ Synchronization protocols can be used to loosely synchronize nodes
 - ▶ Nodes wake up for a short period and check for channel activity
 - ▶ Return to sleep if no activity detected

Distributed Synchronous Periodic Resume

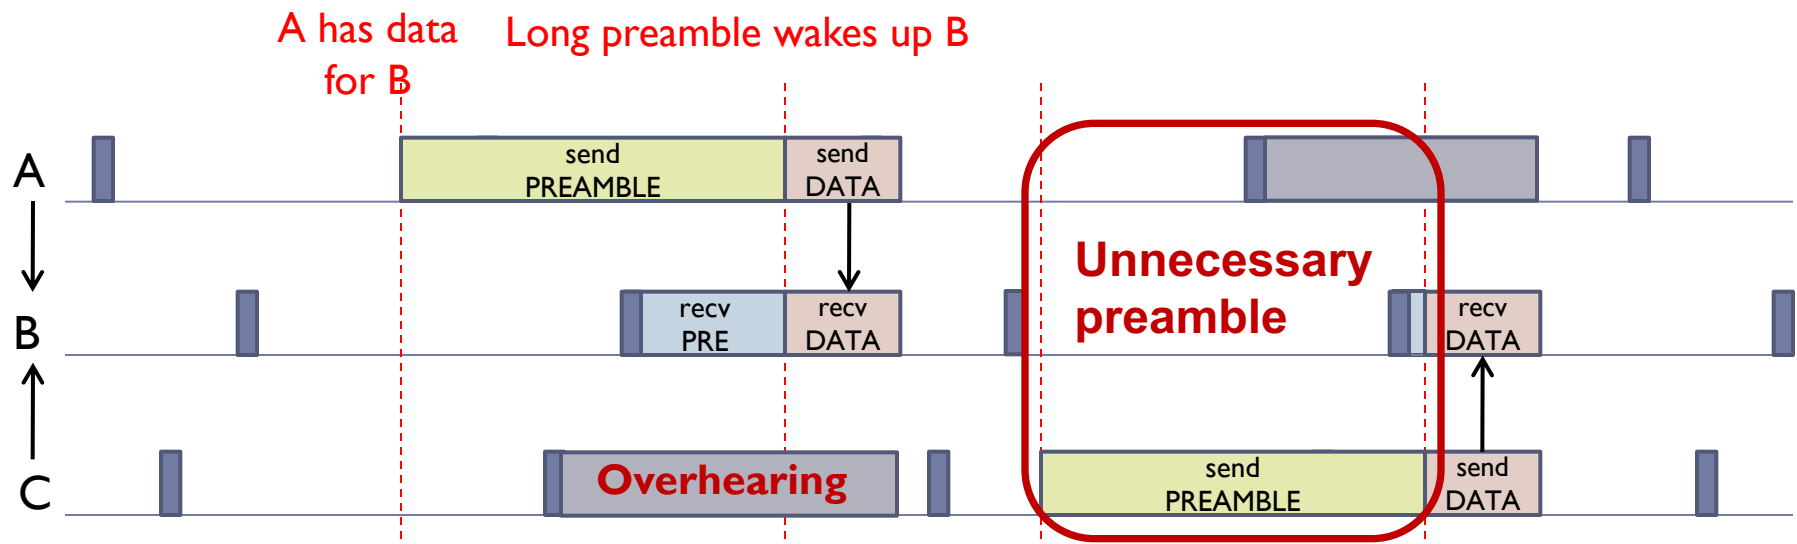

- ▶ Persistent loose synchronization
 - ▶ Constant, high synchronization overhead

Distributed Synchronous Periodic Resume

► Signaling

- No synchronization overhead
- High signaling overhead
 - Long preambles, all nodes wake up

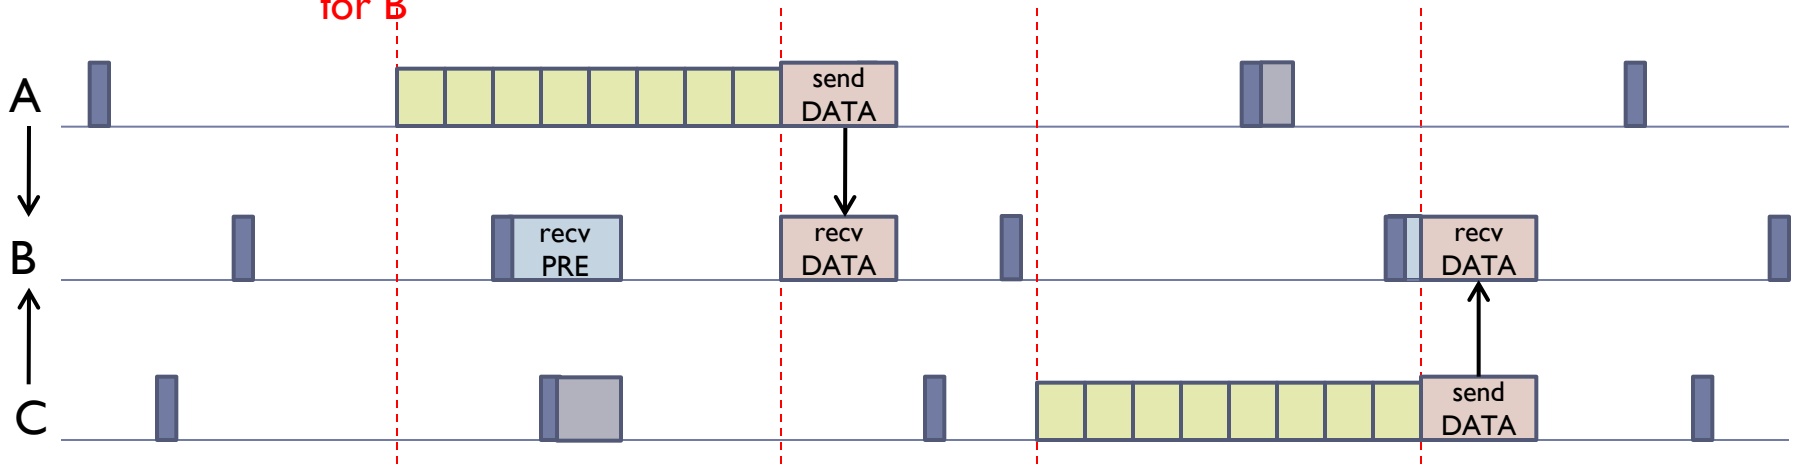

Distributed Synchronous Periodic Resume

► Signaling: Wake-up packets

- Send wake-up packets instead of preamble
- Wake-up packets tell when data is starting so that receiver can go back to sleep as soon as it receives one wake-up packet

A has data
for B

Distributed Synchronous Periodic Resume

- ▶ **Signaling: Multiple send**
 - ▶ Send data several times
 - ▶ Receiver can listen at any time and get all data
- ▶ **Problem with all approaches**
 - ▶ Communication costs are mostly paid by the sender
 - ▶ The amount of time the sender spends transmitting may be much longer than the actual data length

Synchronous Periodic Resume

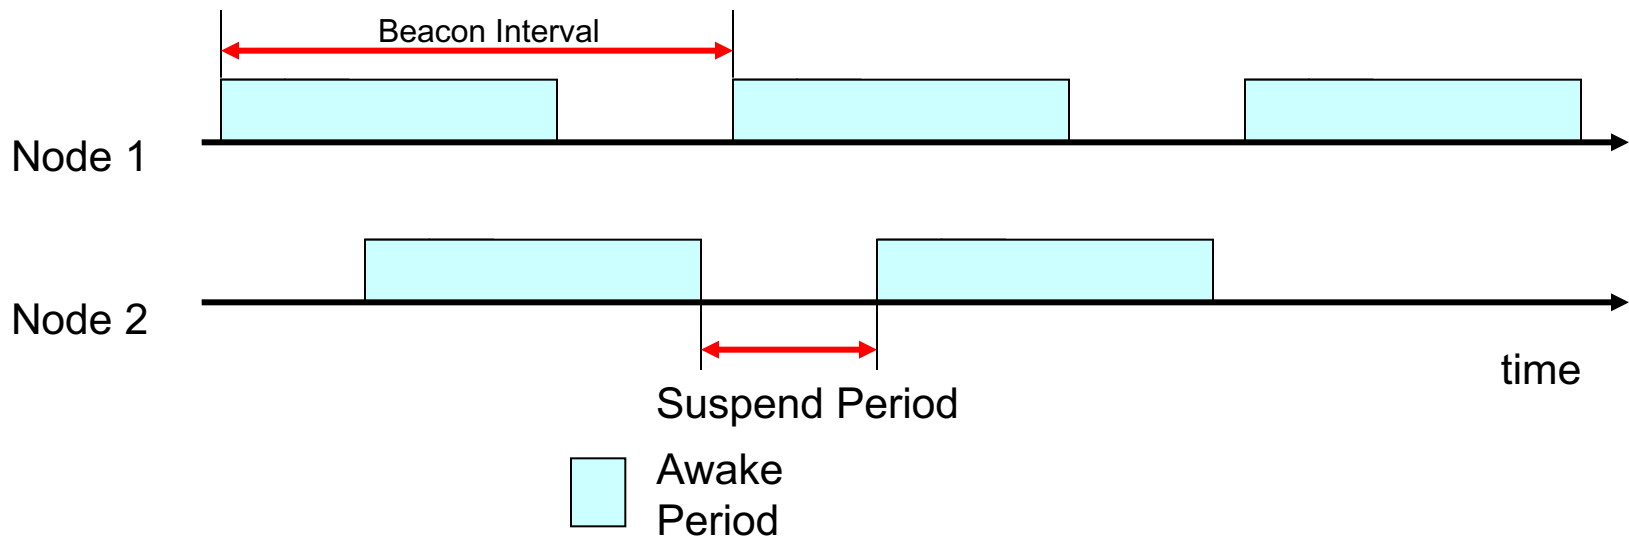

► Problems

- Maintaining synchronization may be difficult
- Throughput is limited by the size of the notification window
 - If the notification window is too small, packets get buffered
 - Buffers may eventually overflow

Asynchronous Periodic Resume

► Approach

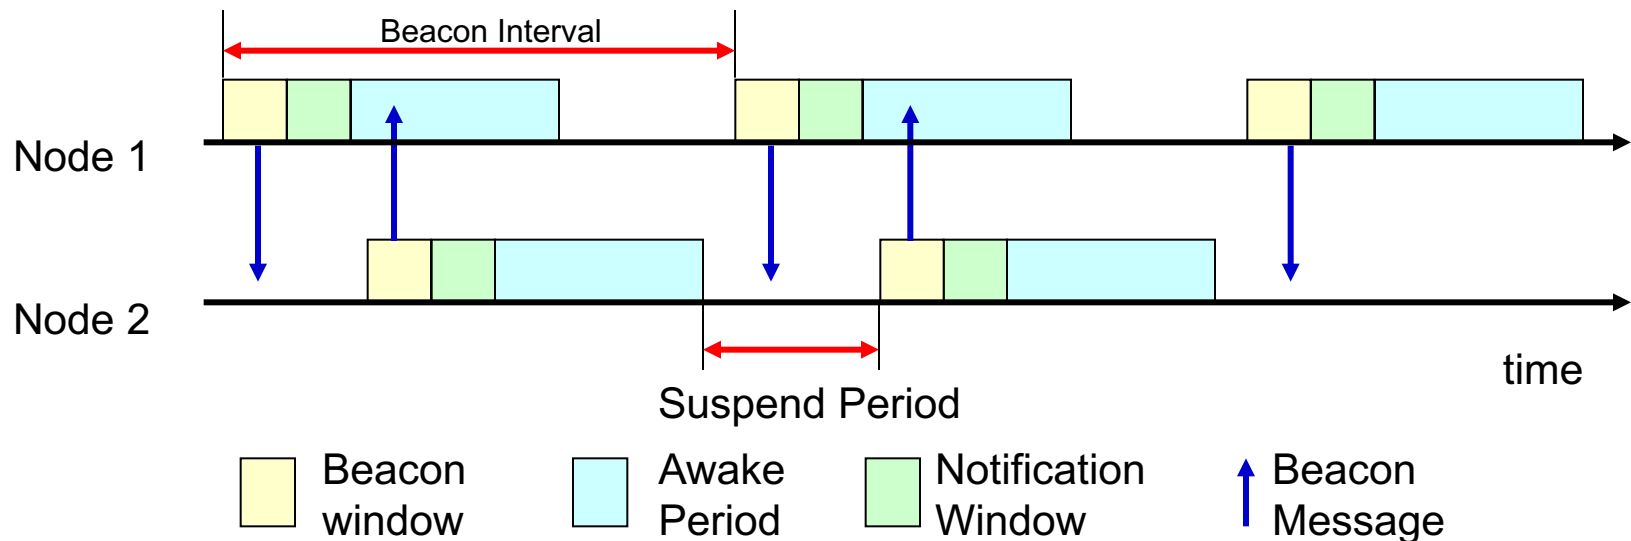

- Stay awake longer to guarantee overlap of awake periods
- Overlap is guaranteed if the awake periods are more than half the beacon period

Asynchronous Periodic Resume

► Basic protocol

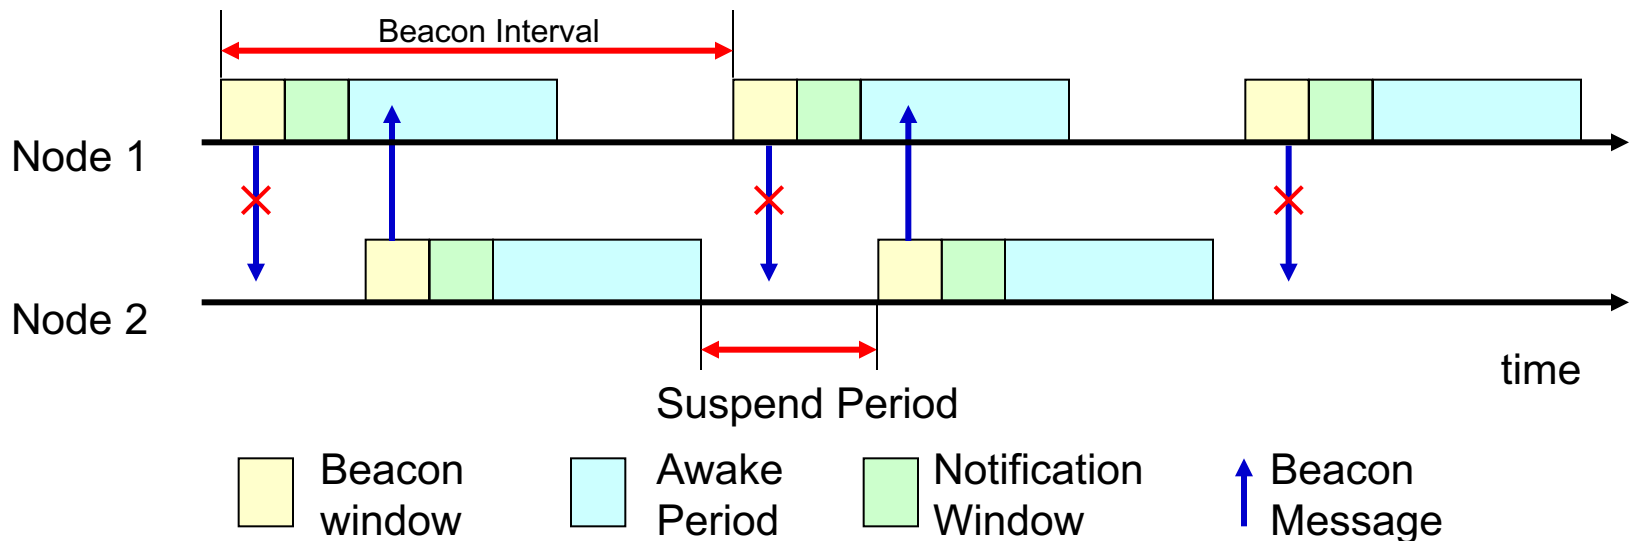

- Use beacon messages at the start of awake periods
- Some protocols use notification messages (similar to ATIM)

Asynchronous Periodic Resume

► Problem

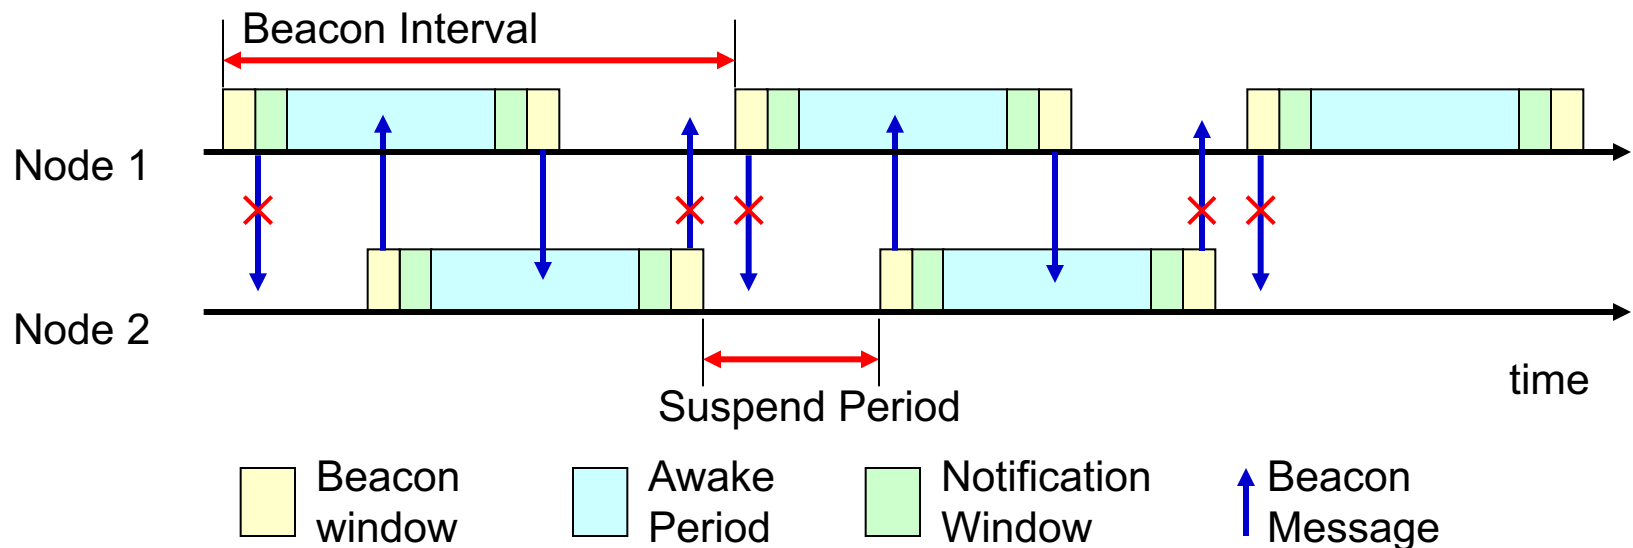

- No guarantee that all nodes will hear each other's beacon or notification messages

Asynchronous Periodic Resume

► Solution

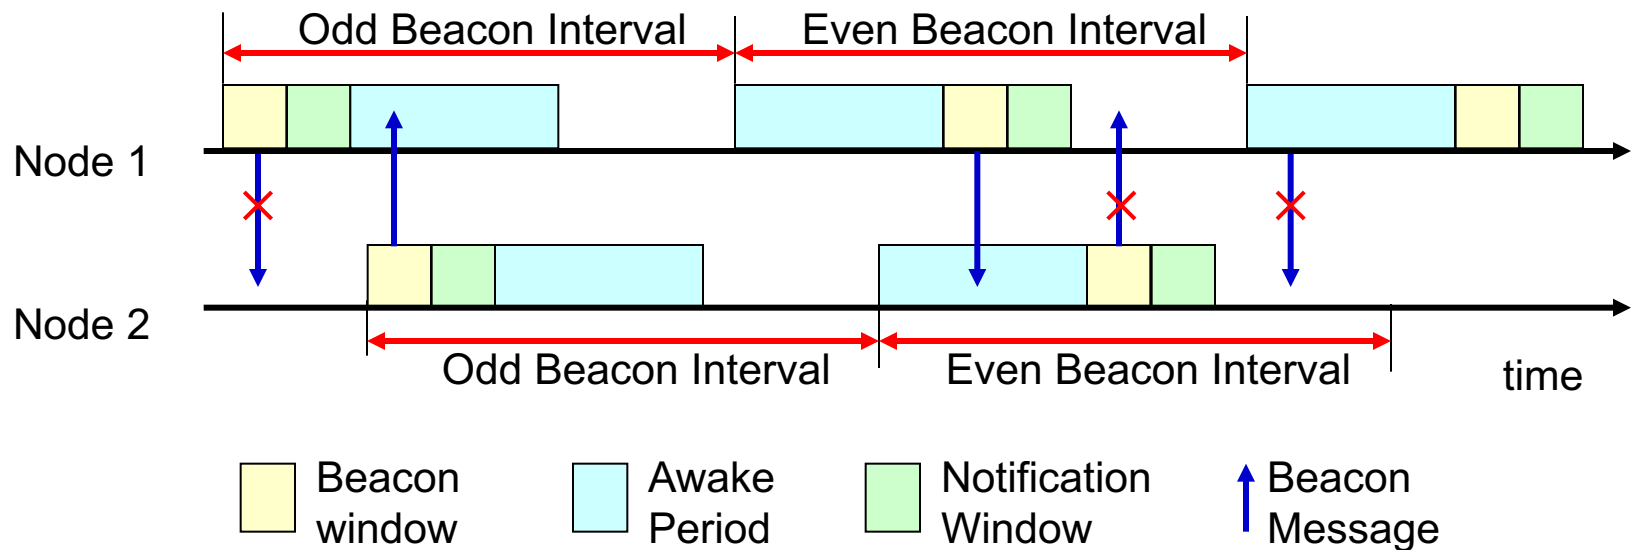

- Have a beacon at the beginning and end of the beacon interval

Asynchronous Periodic Resume

▶ Alternate solution

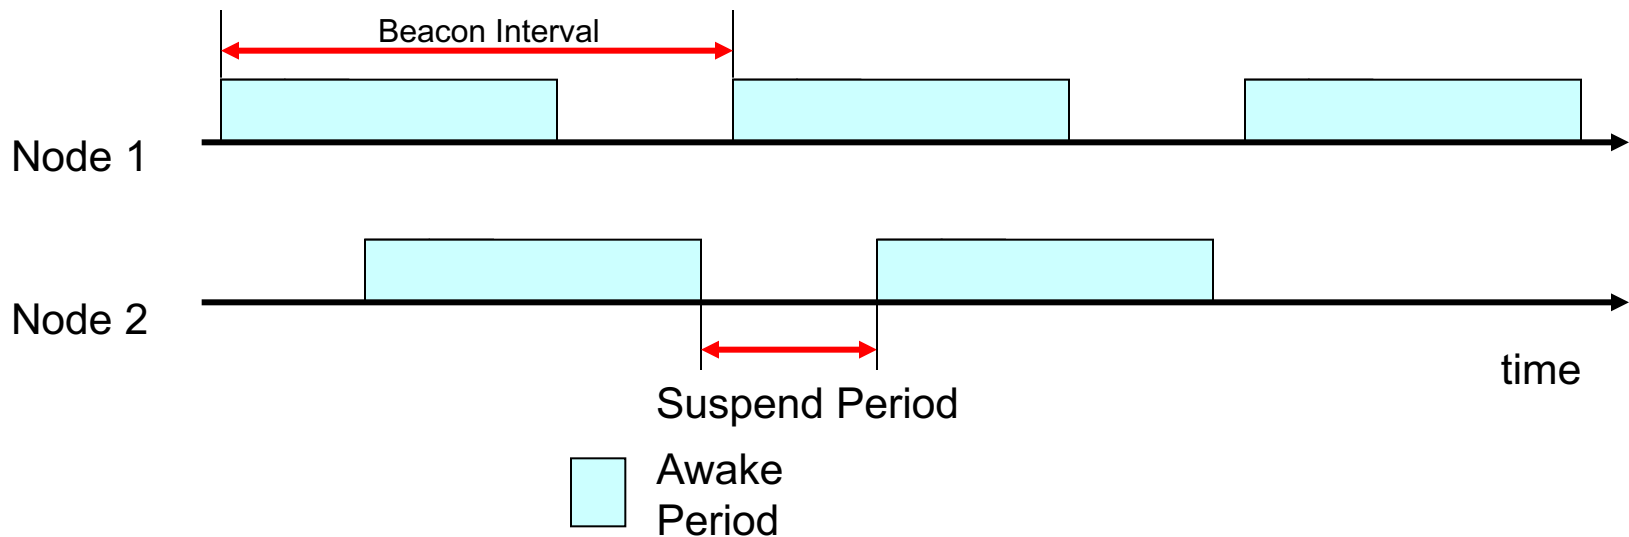

- ▶ Beacon at the beginning of odd periods
- ▶ Beacon at the end of even periods

Asynchronous Periodic Resume

► Problem

- Nodes stay awake more than half the time
- Wastes too much energy!

Asynchronous Periodic Resume

► Reduce awake time

- Do not wake up every beacon interval
- Delay depends on number of overlapping intervals

Asynchronous Periodic Resume

► Randomized Approach

► Birthday protocol

- Randomly select a slot to wake up in with a given probability
- Advantage
 - Good average case performance
- Disadvantage
 - No bounds on worst-case discovery latency

► Extended sleep

-
- Figure 1 illustrates the Beacon Interval. The diagram shows two nodes, Node 1 and Node 2, over time. Node 1 has a periodic beacon interval (indicated by a red double-headed arrow). Node 2 receives beacon messages (blue upward arrows) and sends notifications (blue downward arrows) during its awake periods (light blue). Beacon windows (yellow) and notification windows (green) are shown for both nodes. Red 'X' marks indicate missed beacon messages.
- Legend:
- Beacon window (yellow box)
 - Awake Period (light blue box)
 - Notification Window (green box)
 - Beacon Message (blue upward arrow)

Asynchronous Periodic Resume

► Quorum

- Increase number of beacon intervals in cycle (n)
- Increase number of awake periods ($2n - 1$ of n^2)

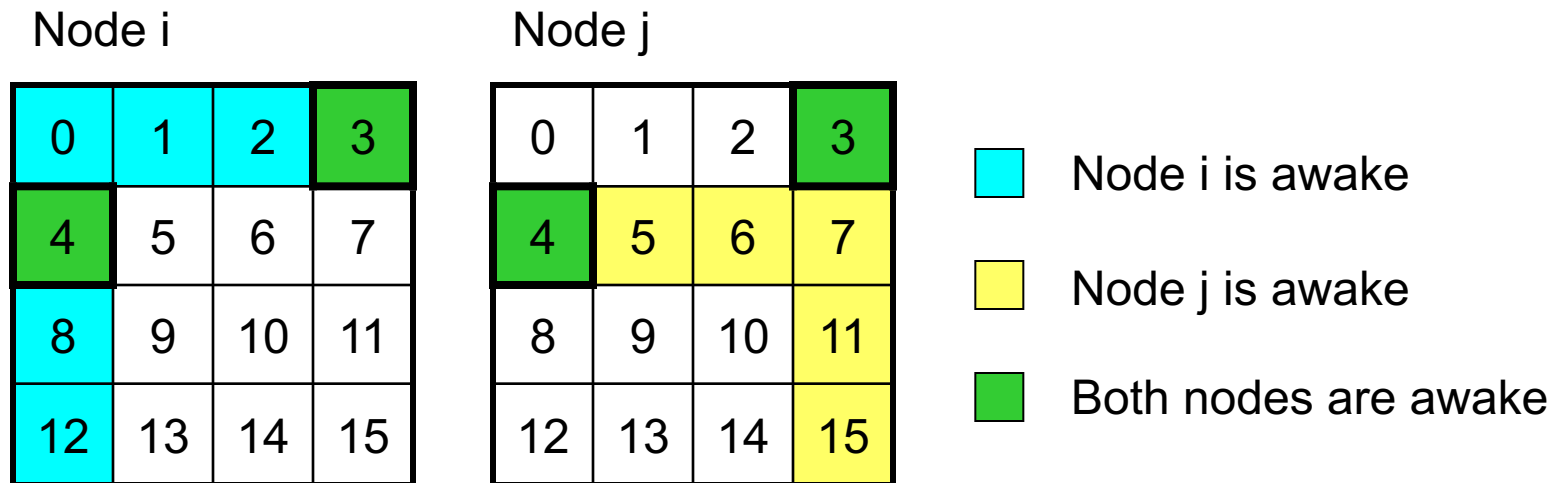

Delay is determined by where the overlap is (worst case n^2)

Asynchronous Periodic Resume

► Quorum

- Example: $n = 4$, $n^2 = 16$, $2n-1 = 7$
 - Two overlapping intervals: delay = $n^2 - 2$

Asynchronous Periodic Resume

► Deterministic

- Find a feasible overlapping pattern
 - Guarantee at least one overlapping interval
 - Requires knowledge of number of nodes

Asynchronous Periodic Resume

► Deterministic: Prime-based

► Disco

- Pick two primes p_1 and p_2
- Wake up every p_1 and p_2 slot
- Guarantees discovery in $p_1 \times p_2$ slots

Asynchronous Periodic Resume

► Deterministic: Prime-based

► U-Connect

- Select 1 prime p
- Wake up every p th slot and $(p-1)/2$ slots every p^2 slots
- Overlap is guaranteed within p^2 slots

Asynchronous Periodic Resume

► Searchlight

- Have a **deterministic** discovery schedule that has a **pseudo-random** component

Asynchronous Periodic Resume

▶ Searchlight

- ▶ Two slots per t slots (period)
 - ▶ Anchor slot: Keep one slot fixed at slot 0
 - ▶ Probe slot: Move around the other slot sequentially
- ▶ Guaranteed overlap in $t^*t/2$ slots
 - ▶ Based on the time needed to ensure a probe-anchor overlap
- ▶ Probe-probe overlap can also lead to discovery
 - ▶ Sequential scanning means less chance of a probe-probe overlap

Discovery through anchor-probe overlap

Asynchronous Periodic Resume

▶ Searchlight

- ▶ Extension: randomized probing
 - ▶ Move the probe slot randomly
- ▶ Each node randomly chooses a schedule for its probe slot that repeats every $(t \cdot t/2)$ slots
 - ▶ Schedules of two nodes appear random to each other
- ▶ Advantage
 - ▶ Retains the same worst-case bound
 - ▶ Improves average case performance

Discovery through probe-probe overlap

Asynchronous Periodic Resume

► Challenges

- Reducing time spent awake
- Reducing delay
- No support for broadcast
 - None of the current approaches provide an interval where all nodes are awake
