

ECE 220: Computer Systems & Programming

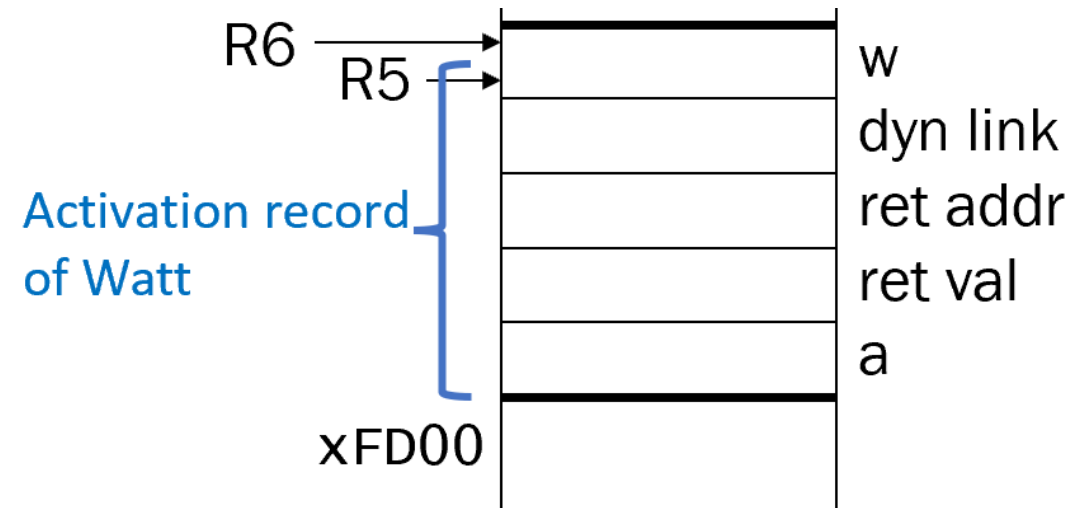

Lecture 9: Pointers and Arrays

Adapted from Prof. Moon's slides

Last class: Run-time Stack and Stack Frame/Activation Records

```
int Watt(int a)
{
    int w;
    ...
    w = volta(w,10);
    ...
    return w;
}

int volta(int q, int r)
{
    int k;
    int m;
    ...
    return k;
}
```

1. Caller setup (push callee's arguments onto stack)
2. Pass control to callee

```
int Watt(int a)
{
    int w;
    ...
    w = volta(w,10);
    ...
    return w;
}

int volta(int q, int r)
{
    int k;
    int m;
    ...
    return k;
}
```

3. Callee setup (push bookkeeping info and local variables onto stack)
4. Execute function

```

int Watt(int a)
{
    int w;
    ...
    w = volta(w,10);
    ...
    return w;
}

int volta(int q, int r)
{
    int k;
    int m;
    ...
    return k;
}

```

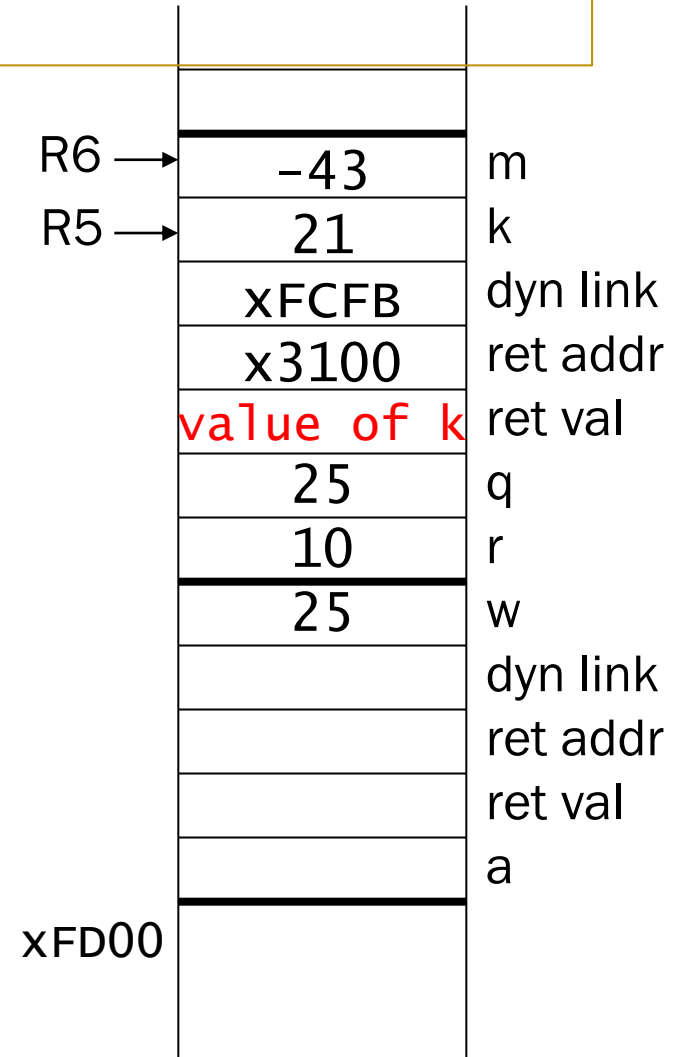

5. Callee tear-down (update return value, pop local variables, caller's frame pointer and return address from stack)

6. Return to caller

Credit: Prof. moon

```
int watt(int a)
{
    int w;
    ...
    w = volta(w,10);
    ...
    return w;
}

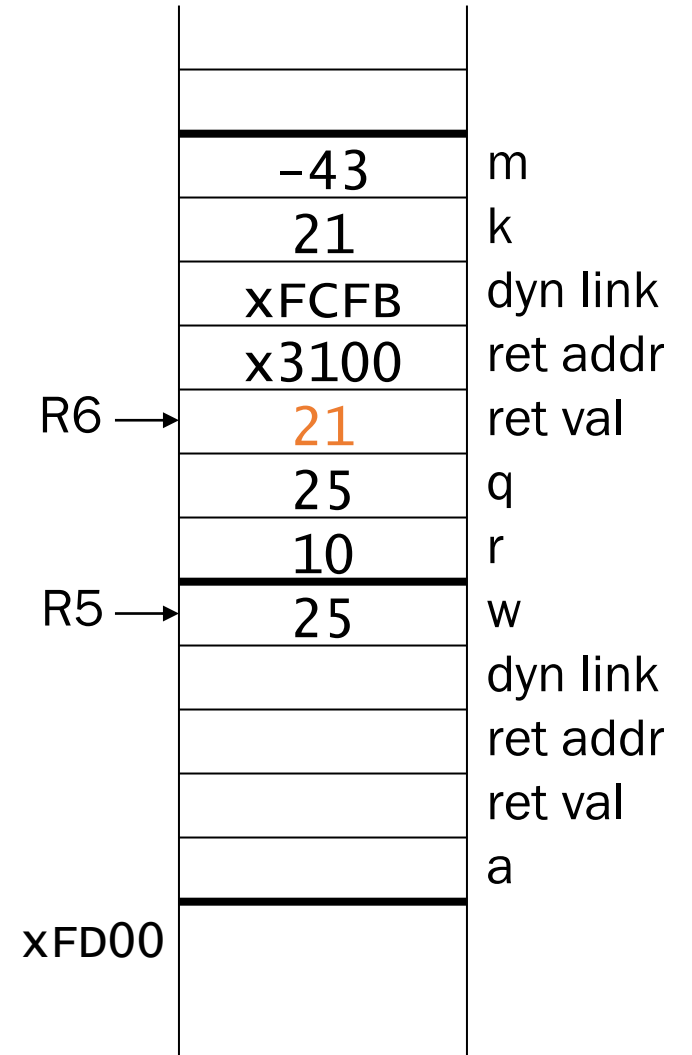

int volta(int q, int r)
{
    int k;
    int m;
    ...
    return k;
}
```

7. Caller tear-down (pop callee's return value and arguments from stack)

```
int Watt(int a)
{
    int w;
    ...
    w = volta(w,10);
    ...
    return w;
}

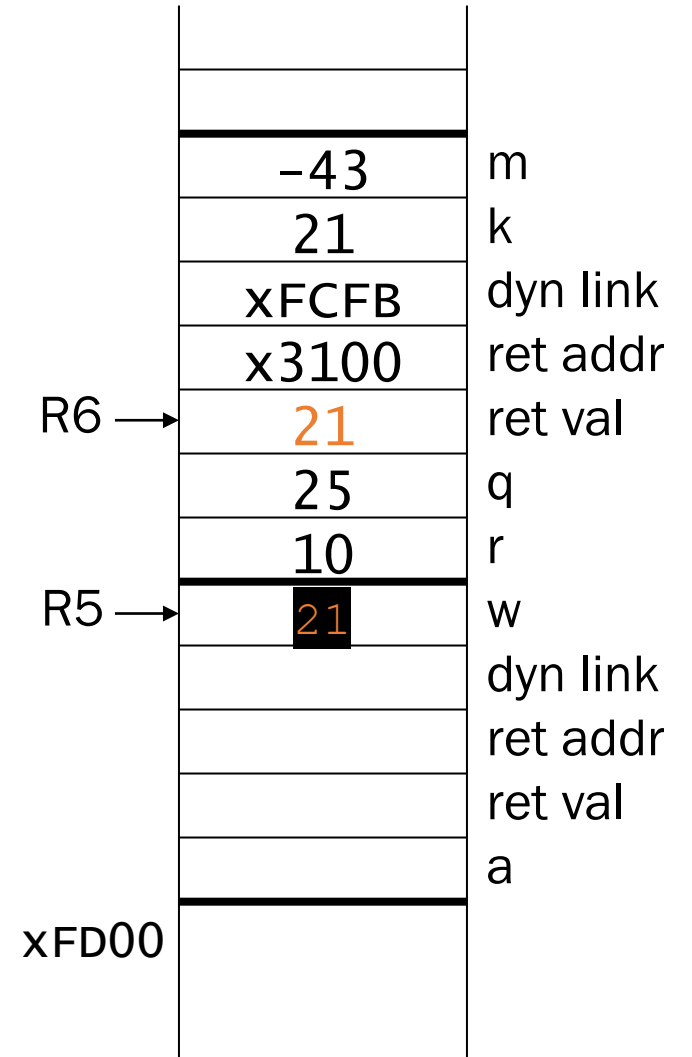

int volta(int q, int r)
{
    int k;
    int m;
    ...
    return k;
}
```

7. Caller tear-down (pop callee's return value and arguments from stack)

```
int Watt(int a)
{
    int w;
    ...
    w = volta(w,10);
    ...
    return w;
}

int volta(int q, int r)
{
    int k;
    int m;
    ...
    return k;
}
```

Swap Function

```
void Swap(int firstVal, int secondVal);
int main()
{
    int valueA = 3;
    int valueB = 4;

    Swap(valueA, valueB);
}

void Swap(int firstVal, int secondVal)
{
    int tempVal;

    tempVal = firstVal;
    firstVal = secondVal;
    secondVal = tempVal;
}
```

Goal:

Swap valueA and valueB in main.

Swap Function – Activation Record

```
int main(){
    int valueA = 3;
    int valueB = 4;
    Swap(valueA, valueB);
}
void Swap(int firstVal, int secondVal){
    int tempVal;
    tempVal = firstVal;
    firstVal = secondVal;
    secondVal = tempVal;
}
```

- Swap needs addresses of variables (valueA and valueB) outside its own activation record. Pointers solve this problem!

Solution:

```
void NewSwap(int *firstVal, int *secondVal);

int main()
{
    int valueA = 1;
    int valueB = 2;

    NewSwap(&valueA, &valueB);
}

void NewSwap(int *firstVal, int *secondVal)
{
    int tempVal;

    tempVal = *firstVal;
    *firstVal = *secondVal;
    *secondVal = tempVal;
}
```

Pointers in C

Declaration

```
int *ptr; /* ptr is a pointer to an int */  
or int* ptr;
```

A pointer in C is always a pointer to a particular data type:
int*, double*, char*, etc.

Operators

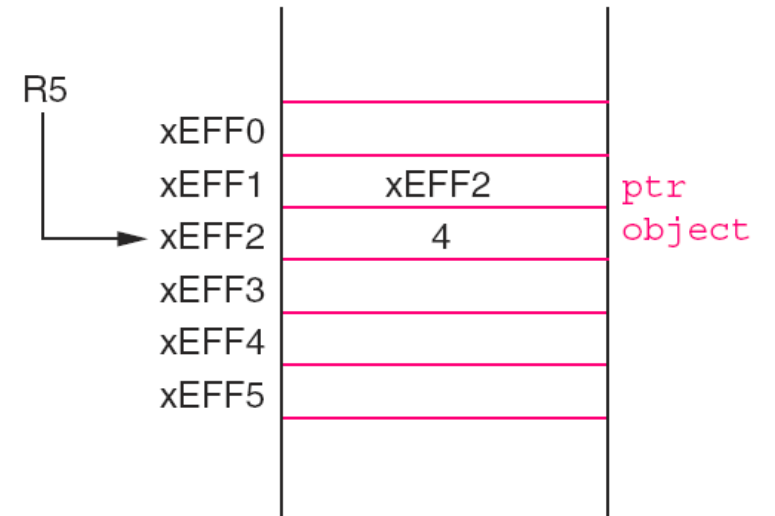

*ptr → dereference operator: returns the value pointed to by ptr. It also allows us to manipulate the value pointed by ptr

&val → address operator: returns the address of variable **val**

‘*’ used in different purposes

Pointers in LC3

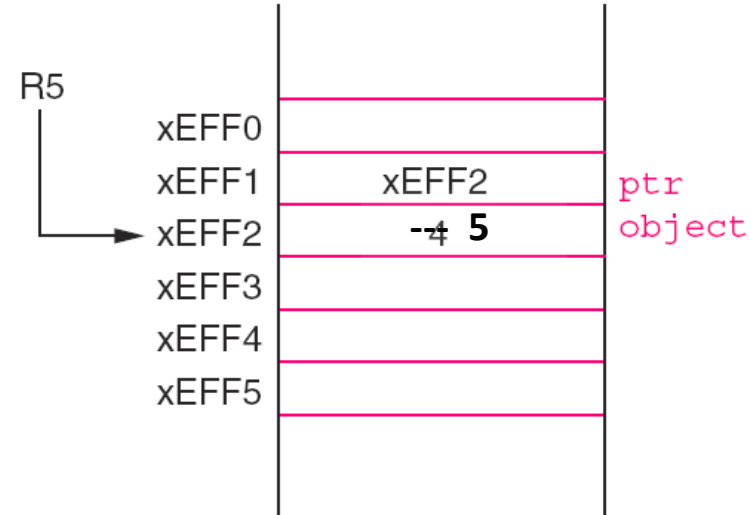

```
int object;  
int *ptr;  
  
object = 4;  
ptr = &object;
```

```
AND R0, R0, #0 ; Clear R0  
ADD R0, R0, #4 ; R0 = 4  
STR R0, R5, #0 ; Object = 4;  
  
ADD R0, R5, #0 ; Generate memory address of object  
STR R0, R5, #-1 ; Ptr = &object;
```

Pointers in LC3

`*ptr = *ptr + 1; ??`

```
LDR  R0, R5, #-1 ; R0 contains the value of ptr
LDR  R1, R0, #0  ; R1 <- *ptr
ADD  R1, R1, #1  ; *ptr + 1
STR  R1, R0, #0  ; *ptr = *ptr + 1;
```

Solve Swap Problem

```
void Swap(int firstVal, int secondVal);
int main()
{
    int valueA = 1;
    int valueB = 2;

    Swap(valueA, valueB);
}

void Swap(int firstVal, int secondVal)
{
    int tempVal;

    tempVal = firstVal;
    firstVal = secondVal;
    secondVal = tempVal;
}
```

 call by value

```
void NewSwap(int *firstVal, int *secondVal);
int main()
{
    int valueA = 1;
    int valueB = 2;

    NewSwap(&valueA, &valueB);
}

void NewSwap(int *firstVal, int *secondVal)
{
    int tempVal;

    tempVal = *firstVal;
    *firstVal = *secondVal;
    *secondVal = tempVal;
}
```

 call by reference

New Swap – Activation Record

```
void NewSwap(int *firstVal, int *secondVal)
{
    int tempVal;

    tempVal = *firstVal;
    *firstVal = *secondVal;
    *secondVal = tempVal;
}
```

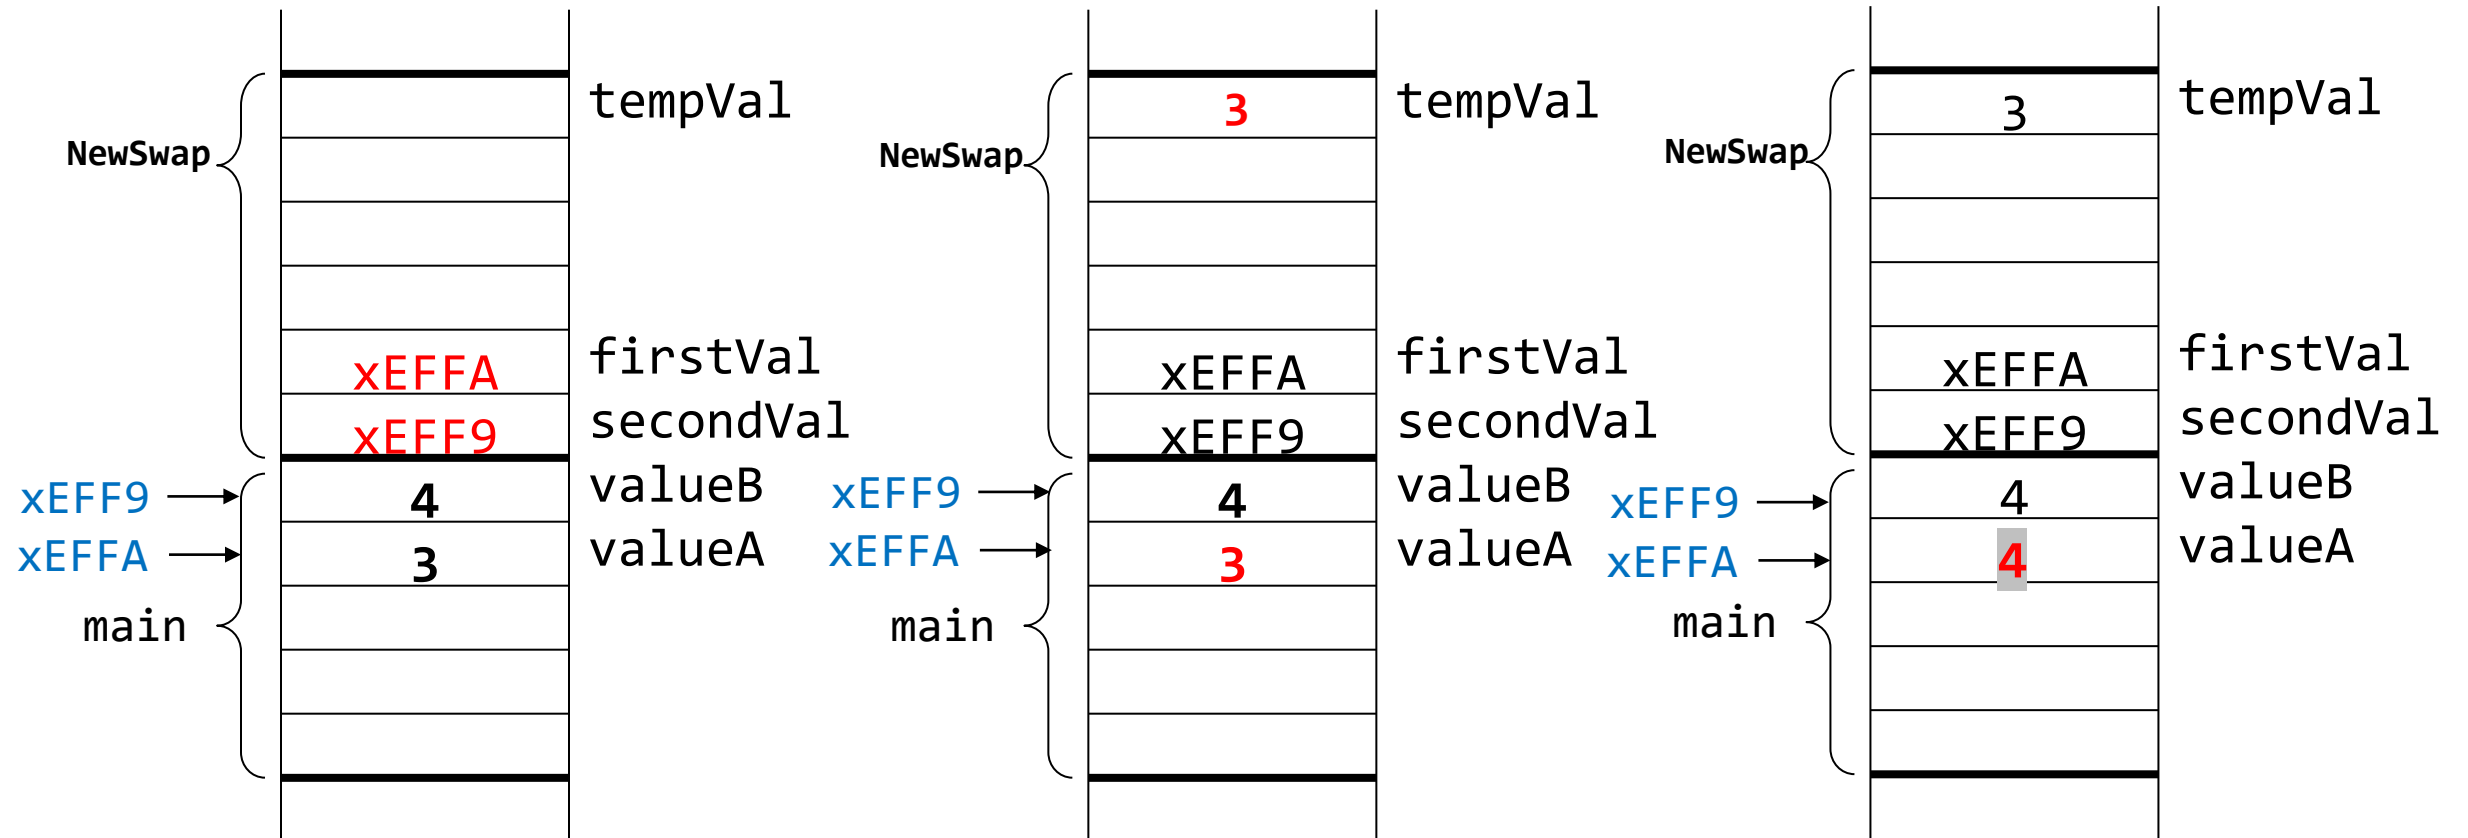

```
int main(){
```

...

```
NewSwap(&valueA, &valueB);
```

```
tempVal = *firstVal;
```

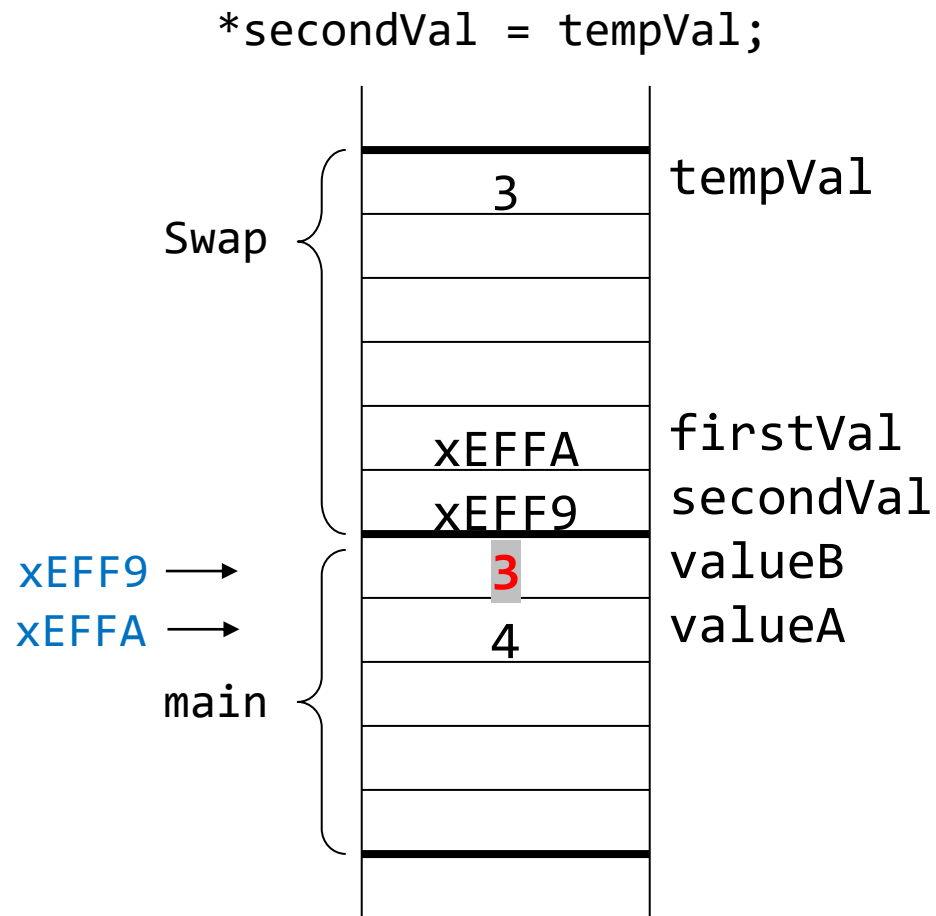

```
*firstVal = *secondVal;
```

New Swap – Activation Record (continued)

```
void NewSwap(int *firstVal, int *secondVal)
{
    int tempVal;

    tempVal = *firstVal;
    *firstVal = *secondVal;
    *secondVal = tempVal;
}
```

Heads up: *??

```
int main()
{
    int valueA = 1;
    int valueB = 2;

    NewSwap(&valueA, &valueB);
}

void NewSwap(int ①*firstVal, int ②*secondVal)
{
    int tempVal;
    tempVal = ③*firstVal;
    ④*firstVal = ⑤*secondVal;
    ⑥*secondVal = tempVal;
}
```

`int *firstVal = &valueA;`
`int *secondVal = &valueB;`

Which * is used for the dereference operator?

3,4,5,6

Which * is used for declaring a pointer variable?

1,2

`int *firstVal;`
`firstVal = &valueA;`
`int *secondVal;`
`secondVal = &valueB;`

More on Pointers

- Null pointer: a pointer that points to nothing

```
int *ptr;  
int valueA;
```

```
ptr = &valueA;  
printf("x%X\n", ptr);
```

x1B2F5F3C

x0

```
ptr = NULL;  
printf("x%X\n", ptr);
```

- Demystifying ‘&’ in scanf

```
int input;  
scanf("%d", &input);
```

scanf needs to update the variable with data from the keyboard. Therefore, it needs the address of the variable, not its value.

Common Mistakes on Pointers

```
int val = 5;  
char *ptr;  
ptr = &val;
```

Type mismatch

```
int *ptr;  
*ptr = 4;
```

Dereferencing a pointer before initialized

```
int *ptr;  
ptr = 4;
```

Pointing memory address "4"

Double Pointer

```
int x = 10;
```

```
int *p;
```

```
p = &x;
```

```
int **pp;
```

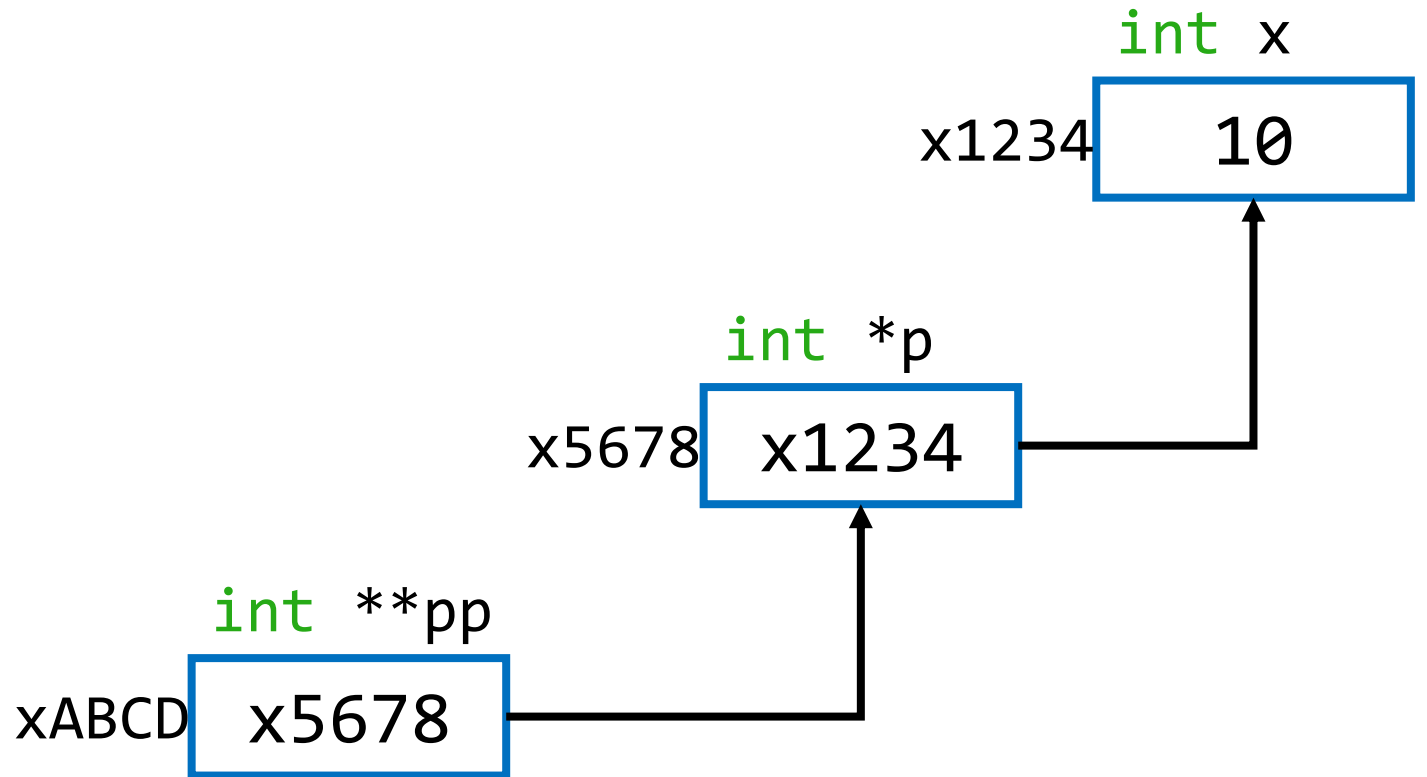

```
pp = &p;
```

```
printf("x%X\n", &pp);
```

```
printf("x%X\n", pp);
```

```
printf("x%X\n", *pp);
```

```
printf("%d\n", **pp);
```

Double Pointer

```
int x = 10;
```

```
int *p;
```

```
p = &x;
```

```
int **pp;
```

```
pp = &p;
```

```
printf("x%X\n", &pp);
```

```
printf("x%X\n", pp);
```

```
printf("x%X\n", *pp);
```

```
printf("%d\n", **pp);
```

Array

- How do we allocate a group of memory locations?
 - character string
 - table of numbers
- Problem1:
What if 100 numbers?
- Problem2:
How to write a loop to process each number?

```
int stdn0;  
int stdn1;  
int stdn2;  
int stdn3;  
.  
.  
.
```

- Solution: Array

```
int stdn[100];
```

```
stdn[0]=90;
```

max/min index?

Array Syntax

- Declaration

```
type variable[num_elements];
```

all array elements
are of the same type

- Array reference

```
variable[index];
```

i-th element of array (starting with zero);
no limit checking at compile-time or run-time

Example

```
int grid[10] = {2,10,21,3,6,1,0,9,11,12};
```

```
grid[6] = grid[3]+1;
```

```
int i;  
for(i=0;i<10;i++)  
    printf("%d\n", grid[i]);
```

```
2  
10  
21  
3  
6  
1  
4  
9  
11  
12
```

Array in Activation Record

```
int grid[10];  
int x;  
.  
.  
.
```

*First element (grid[0]) is at *lowest* address of allocated space.

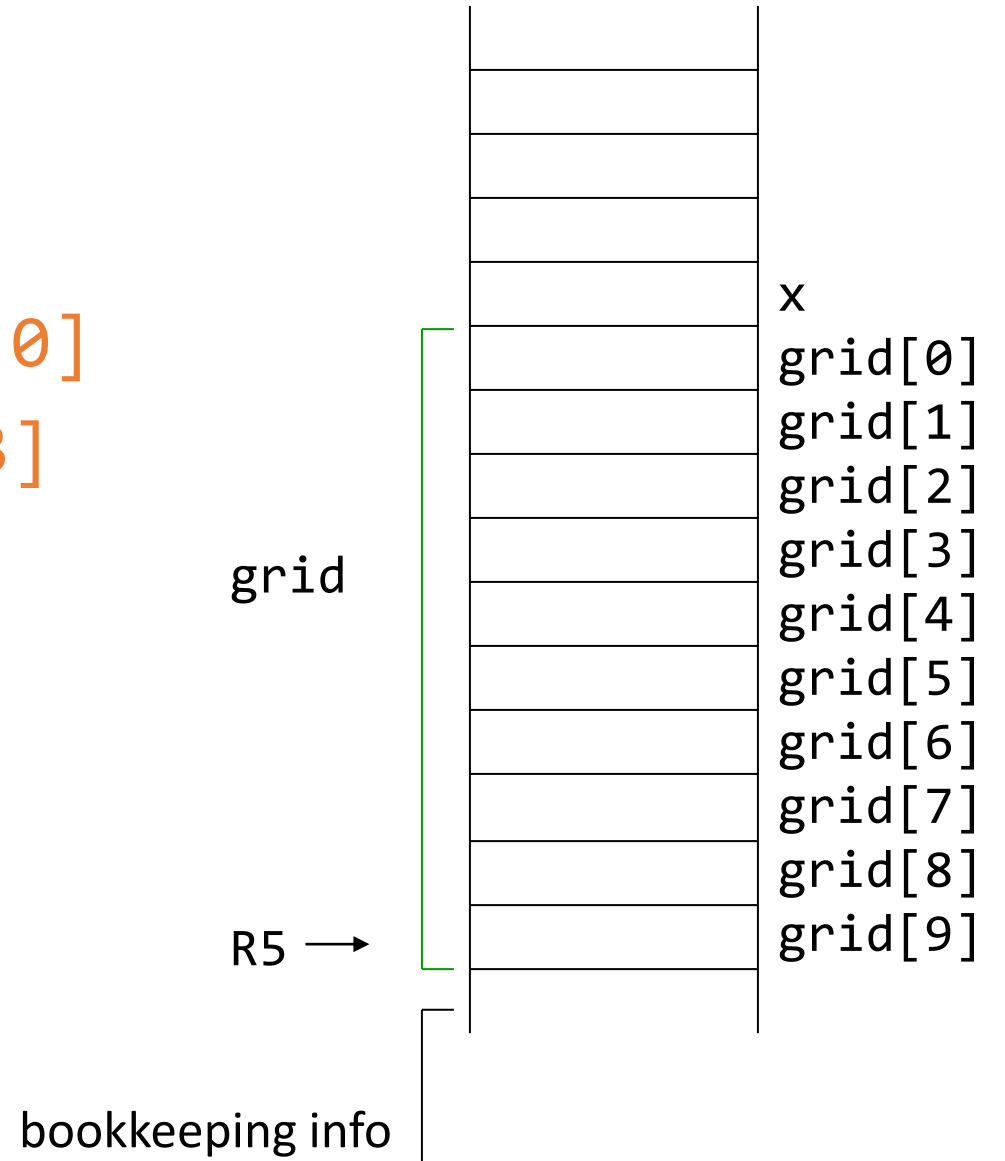

*If grid is the first local variable, then **R5** points to grid[9].

LC-3 for Array References

```
; x = grid[3] + 1
```

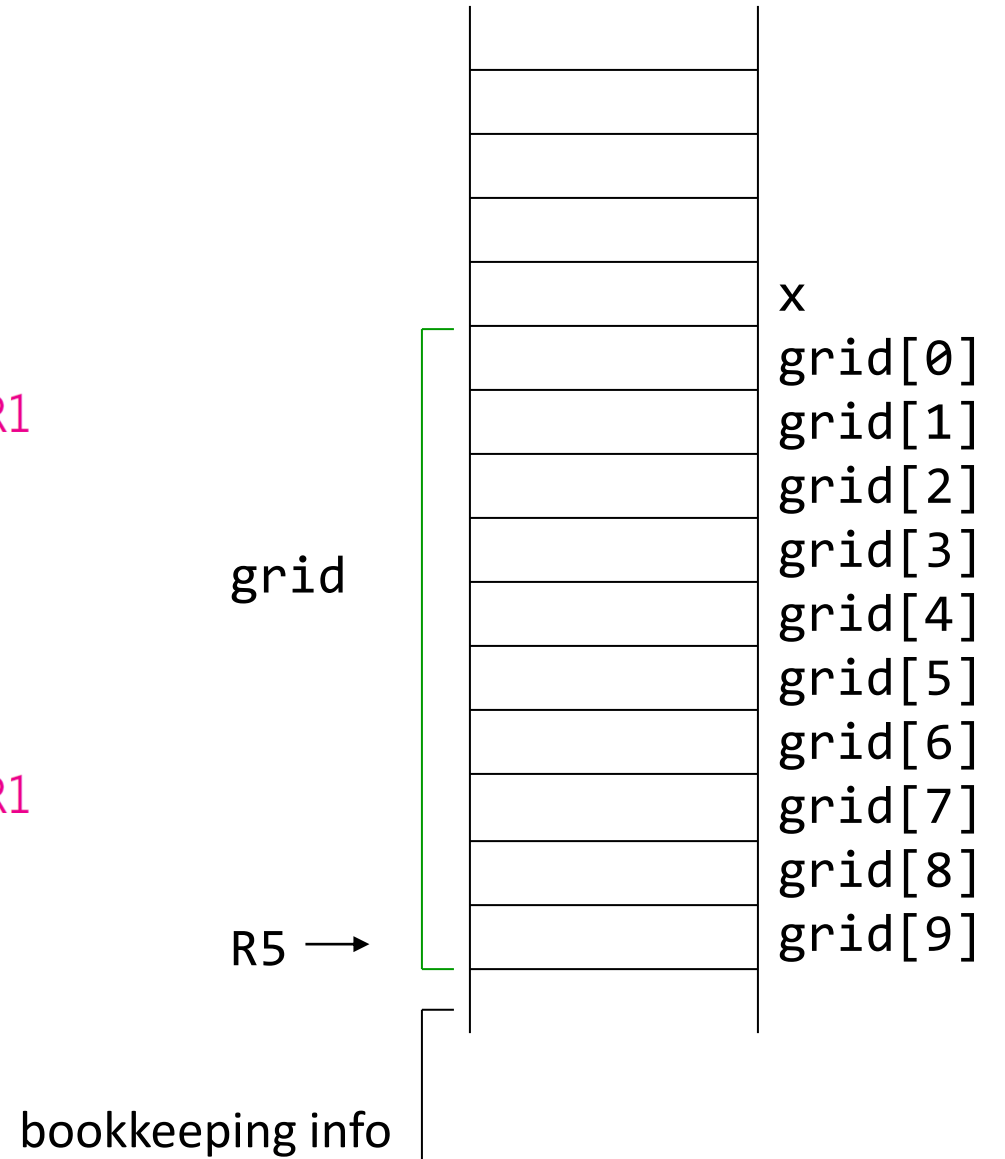

```
ADD R0, R5, #-9      ; R0 = &grid[0]  
LDR R1, R0, #3       ; R1 = grid[3]  
ADD R1, R1, #1       ; plus 1  
STR R1, R5, #-10     ; x = R1
```

LC-3 for Array References

$\text{grid}[x+1] = \text{grid}[x] + 2$

```
LDR R0, R5, #-10 ; Load the value of x
ADD R1, R5, #-9  ; Put the base address of grid into R1
ADD R1, R0, R1   ; Calculate address of grid[x]
LDR R2, R1, #0   ; R2 <-- grid[x]
ADD R2, R2, #2   ; R2 <-- grid[x] + 2
LDR R0, R5, #-10 ; Load the value of x
ADD R0, R0, #1   ; R0 <-- x + 1
ADD R1, R5, #-9  ; Put the base address of grid into R1
ADD R1, R0, R1   ; Calculate address of grid[x+1]
STR R2, R1, #0   ; grid[x+1] = grid[x] + 2;
```

Relationship between Pointers and Arrays

- An array name points to the first element in the array.

```
char word[10];  
char *cptr;  
  
cptr = word; // points to word[0]
```

- What is difference?

cptr is a variable, but the name “word” is not a variable.

```
cptr = cptr + 1;  
word = word + 1; // compile error
```

Correspondence between Pointer and Array Notation

```
char word[10];
```

```
char *cptr;
```

```
cptr = word; // points to word[0]
```

- Each line below gives three equivalent expressions:

<code>cptr</code>	<code>word</code>	<code>&word[0]</code>
-------------------	-------------------	---------------------------

<code>(cptr + n)</code>	<code>word + n</code>	<code>&word[n]</code>
-------------------------	-----------------------	---------------------------

<code>*cptr</code>	<code>*word</code>	<code>word[0]</code>
--------------------	--------------------	----------------------

<code>*(cptr + n)</code>	<code>*(word + n)</code>	<code>word[n]</code>
--------------------------	--------------------------	----------------------
