

Your Comments

Do we still get the 80% back on homework? It doesn't seem to be showing that. Also, this is really starting to make sense to me!

I am a little confused about the differences in solid conductors, solid insulators, and instances where there is a combination of both and we need to find the electric field.

I had some difficulty understanding the material, especially the significance of charge density and the induced charges on a conducting sphere.

There were a few times during the pre lecture where they said "The electric field here **MUST** be 0" and I didn't understand why

How do you know what Gaussian surface to use to calculate the electric field produced by a particular object? Like if you're calculating the electric field produced a distance r from solid spherical conductor you would use a concentric sphere as the Gaussian surface. Then for instance for a cube, would you use a concentric cube?

Sometimes I get confused as to what radius to plug in for volumes and areas. Could we go over when to use the radius of the charge and when to use the radius of the Gaussian surface?

Electricity & Magnetism

Lecture 4

Today's Concepts:

A) Conductors

B) Using Gauss' Law

Conductors and Insulators

Conductors = charges free to move

e.g. metals

Insulators = charges fixed

e.g. glass

Define: Conductors = Charges Free to Move

Claim: $E = 0$ inside any conductor at equilibrium

Charges in conductor move to make E field zero inside. (Induced charge distribution).

If $E \neq 0$, then charge feels force and moves!

Claim: Excess charge on conductor only on surface at equilibrium

Why?

➤ Apply Gauss' Law

➤ Take Gaussian surface to be just inside conductor surface

➤ $E = 0$ everywhere inside conductor $\rightarrow \oint_{\text{surface}} \vec{E} \cdot d\vec{A} = 0$

➤ Gauss' Law: $\oint_{\text{surface}} \vec{E} \cdot d\vec{A} = \frac{Q_{\text{enc}}}{\epsilon_0} \rightarrow Q_{\text{enc}} = 0$

[SIMULATION 2](#)

Gauss' Law + Conductors + Induced Charges

$$\oint_{\text{surface}} \vec{E} \cdot d\vec{A} = \frac{Q_{enc}}{\epsilon_0}$$

ALWAYS TRUE!

If choose a **Gaussian surface** that is entirely in metal, then $E = 0$ so $Q_{enclosed}$ must also be zero!

$$E = \frac{Q_{enc}}{A\epsilon_0}$$

How Does This Work?

Charges in conductor move to surfaces to make $Q_{enclosed} = 0$.

We say charge is induced on the surfaces of conductors

Charge in Cavity of Conductor

A particle with charge $-Q$ is placed in the center of an uncharged conducting hollow sphere. How much charge will be induced on the inner and outer surfaces of the sphere?

- A) inner = $-Q$, outer = $+Q$
- B) inner = $-Q/2$, outer = $+Q/2$
- C) inner = 0, outer = 0
- D) inner = $+Q/2$, outer = $-Q/2$
- E) inner = $+Q$, outer = $-Q$

➤ Gauss' Law: $\oint_{surface} \vec{E} \cdot d\vec{A} = \frac{Q_{enc}}{\epsilon_0}$

Since $E = 0$ in conductor

$$0 = \frac{Q_{enc}}{\epsilon_0}$$

$$0 = -Q + Q_{inner}$$

Since conductor is uncharged

$$Q_{inner} + Q_{outer} = 0$$

$$Q_{outer} = -Q_{inner}$$

Infinite Cylinders

A long thin wire has a uniform positive charge density of 2.5 C/m . Concentric with the wire is a long thick conducting cylinder, with inner radius 3 cm , and outer radius 5 cm . The conducting cylinder has a net linear charge density of -4 C/m .

What is the linear charge density of the induced charge on the inner surface of the conducting cylinder (λ_i) and on the outer surface (λ_o)?

λ_i :	+2.5 C/m	-4 C/m	0	-2.5 C/m
λ_o :	-6.5 C/m	0	-4 C/m	+2.5 C/m
	A	B	C	D

-2.5 C/m
-1.5 C/m
E

Gauss' Law

I'm confused with how to determine which gaussian surface is best suited to calculate an electric field

$$\int \vec{E} \cdot d\vec{A} = \frac{Q_{enc}}{\epsilon_0}$$

ALWAYS TRUE!

In cases with symmetry can pull E outside and get $E = \frac{Q_{enc}}{A\epsilon_0}$

In General, integral to calculate flux is difficult.... and not useful!

To use **Gauss' Law** to calculate E , need to choose surface carefully!

1) Want E to be constant and equal to value at location of interest

OR

2) Want $E \cdot A = 0$ so doesn't add to integral

Gauss' Law Symmetries

$$\int \vec{E} \cdot d\vec{A} = \frac{Q_{enc}}{\epsilon_0}$$

ALWAYS TRUE!

In cases with symmetry can pull E outside and get $E = \frac{Q_{enc}}{A\epsilon_0}$

Spherical

$$A = 4\pi r^2$$

$$E = \frac{Q_{enc}}{4\pi r^2 \epsilon_0}$$

Cylindrical

$$A = 2\pi rL$$

$$E = \frac{\lambda}{2\pi r \epsilon_0}$$

Planar

$$A = 2\pi r^2$$

$$E = \frac{\sigma}{2\epsilon_0}$$

CheckPoint 1

2) You are told to use Gauss' Law to calculate the electric field at a distance R away from a charged cube of dimension a . Which of the following Gaussian surfaces is best suited for this purpose?

(A)

(B)

(C)

D) The field cannot be calculated using Gauss' Law

E) None of the above

THE CUBE HAS NO GLOBAL SYMMETRY!

THE FIELD AT THE FACE OF THE CUBE

IS NOT

PERPENDICULAR OR PARALLEL

3D	POINT	→	SPHERICAL
2D	LINE	→	CYLINDRICAL
1D	PLANE	→	PLANAR

Gaussian Surface Choice: Question 1 (N = 863)

CheckPoint 3.1

4) A positively charged solid conducting sphere is contained within a negatively charged conducting spherical shell as shown. The magnitude of the total charge on each sphere is the same.

What is direction of field between blue and red spheres?

- ☒ The field point radially outward ☐ The field point radially inward ☐ The field is zero

A) Outward

B) Inward

C) Zero

Charged Conducting Sphere and Spherical Shell: Question 1 (N = 860)

Careful: what does **inside** mean?
This is always true for a solid conductor
(within the material of the conductor)
Here we have a charge "inside"

"The field points from the positive charge to the negative charge."

"It must point inward to cancel out the field outward due to the charge inside the shell to completely cancel out the e-field inside the shell"

"The fields cancel out."

CheckPoint 3.3

4) A positively charged solid conducting sphere is contained within a negatively charged conducting spherical shell as shown. The magnitude of the total charge on each sphere is the same.

What is direction of field OUTSIDE the red sphere?

- ☐ The field point radially outward ☐ The field point radially inward ☐ The field is zero

A) Outward

B) Inward

C) Zero

Charged Conducting Sphere and Spherical Shell: Question 3 (N = 860)

CheckPoint 2

- 4) A charged spherical insulator shell has inner radius a and outer radius b . The charge density on the shell is ρ .

What is magnitude of E at dashed line (r)?

Charged Spherical Shell: Question 1 (N = 862)

- A) $\frac{\rho}{\epsilon_0}$ "It is ρ/ϵ_0 because that is the E -field due to the outside of the sphere and the inside must be equal to that in magnitude."
- B) **Zero** "Within $r < a$ there is no charge enclosed."
- C) $\frac{\rho(b^3 - a^3)}{3\epsilon_0 r^2}$ "units work out."
- D) None of above "its something that is $1/r$."

CheckPoint 4

10) In both cases shown below, the colored lines represent positive (blue) and negative (red) charged planes. The magnitudes of the charge per unit area on each plane is the same.

Infinite Sheets of Charge: Question 1 (N = 860)

In which case is E at point P the biggest?

- A) A B) B C) the same

“The electric field in case B is zero, and the electric field in case A is nonzero.”

“The first positive and negatively charged planes in case B both have fields pointing to the right. These are the strongest fields because they're closest to the point P. The rightmost positive field will point to the left, but this will be weaker than either of the two fields pointing to the right, giving an overall greater field magnitude in case B.”

“If you superposition the electric fields, they cancel out in case B so the electric field is the same in both cases.”

Superposition:

Lets do calculation!

Calculation

Point charge $+3Q$ at center of neutral conducting shell of inner radius r_1 and outer radius r_2 .

a) What is E everywhere?

First question: Do we have enough symmetry to use Gauss' Law to determine E ?

Yes, Spherical Symmetry (what does this mean???)

Magnitude of E depends only on R

- A) Direction of E is along \hat{x}
- B) Direction of E is along \hat{y}
- C) Direction of E is along \hat{r}
- D) None of the above

Calculation

Point charge $+3Q$ at center of neutral conducting shell of inner radius r_1 and outer radius r_2 .

A) What is E everywhere?

We know:

magnitude of E is fcn of r
direction of E is along \hat{r}

We can use **Gauss' Law** to determine E

Use **Gaussian surface** = sphere centered on origin

$$\int \vec{E} \cdot d\vec{A} = \frac{Q_{enc}}{\epsilon_0}$$

$r < r_1$

$$\int E dA = \frac{Q_{enc}}{\epsilon_0}$$

$$E 4\pi r^2 = \frac{+3Q}{\epsilon_0}$$

$$E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{r^2}$$

$r_1 < r < r_2$

$$A) \quad E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{r^2}$$

$$B) \quad E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{r_1^2}$$

$$C) \quad E = 0$$

$r > r_2$

$$A) \quad E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{r^2}$$

$$B) \quad E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{(r - r_2)^2}$$

$$C) \quad E = 0$$

Calculation

Point charge $+3Q$ at center of neutral conducting shell of inner radius r_1 and outer radius r_2 .

A) What is E everywhere?

We know:

$$r < r_1 \quad E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{r^2}$$

$$r > r_2$$

$$r_1 < r < r_2 \quad E = 0$$

B) What is charge distribution at r_1 ?

A) $\sigma < 0$

B) $\sigma = 0$

C) $\sigma > 0$

Gauss' Law:

$$E = 0 \rightarrow Q_{enc} = 0 \rightarrow \sigma_1 = \frac{-3Q}{4\pi r_1^2}$$

Similarly:

$$\sigma_2 = \frac{+3Q}{4\pi r_2^2}$$

Calculation

Suppose give conductor a charge of $-Q$

A) What is E everywhere?

B) What are charge distributions at r_1 and r_2 ?

$$\int \vec{E} \cdot d\vec{A} = \frac{Q_{enc}}{\epsilon_0}$$

$$r < r_1$$

A) $E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{r^2}$

B) $E = \frac{1}{4\pi\epsilon_0} \frac{2Q}{r^2}$

C) $E = \frac{1}{4\pi\epsilon_0} \frac{Q}{r^2}$

$$r > r_2$$

A) $E = \frac{1}{4\pi\epsilon_0} \frac{3Q}{r^2}$

B) $E = \frac{1}{4\pi\epsilon_0} \frac{2Q}{r^2}$

C) $E = \frac{1}{4\pi\epsilon_0} \frac{Q}{r^2}$

$$r_1 < r < r_2$$

$$E = 0$$
