

Today:

Combining relativity and quantum mechanics

What is empty space?

What is matter?

Homework 6 due April 10

Term paper draft due April 17

Classical world: "we have found portions of matter with changeless forces (indestructible qualities) and called them elements... The only changes that can remain possible in such a world are spatial changes, movements... SO at last the task of physics is to refer phenomena to inalterable attractive and repulsive forces whose intensity varies with distance. The solubility of this problem is the complete comprehensibility of nature." Helmholtz ~1890.

Quantum world: "The discovery of particles and antiparticles by Dirac has changed our whole outlook on atomic physics.. Up to that time I think every physicist had thought of the elementary particles along the lines of the philosophy of Democritus, namely by considering these elementary particles as unchangeable units which are just given in nature and are always the same thing, they never change, they never can be transmuted into anything else. They are not dynamical systems, they just exist in themselves. After Dirac's discovery everything looked different, because one could ask, why should a proton not sometimes be a proton plus a pair of electrons and positron and so on? ...Thereby the problem of dividing matter had come into a different light."
W. Heisenberg

Quantum mechanics and special relativity

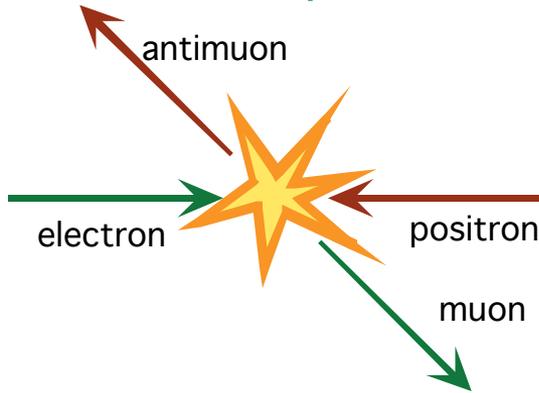

There was some difficulty in combining QM and SR. Roughly, the spread in times for events required by the Uncertainty Principle leaves a tail of events (e.g. particle emission-absorption) seemingly backward in time. In 1928-1930, Dirac found a replacement for the Schroedinger equation, consistent with SR.

- It required that for every particle that carried some conserved quantities, there be another possible particle with the same mass but opposite values of those “charges.” (“antimatter”)
- Dirac was so surprised by this that at first he didn’t believe it and thought the theory was somehow relating the proton and electron.
- The positron (the electron’s antimatter partner) was found in cosmic rays by C. Anderson in 1932.
- An outstanding prediction for theoretical science.

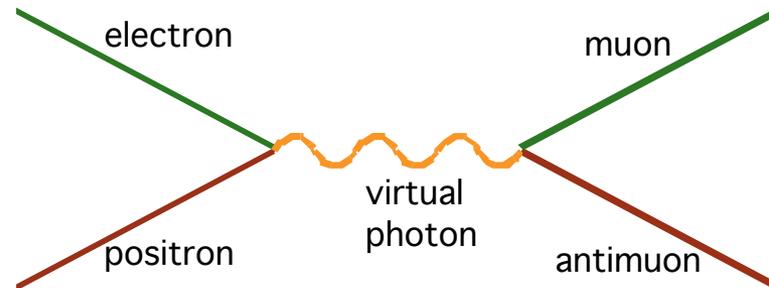

Matter and antimatter can annihilate

- New forms of matter can be produced, as illustrated by “Feynman diagrams”. For example, electrons and positrons can annihilate and produce muons and antimuons:

Annihilation process

Feynman diagram

- Any particle-antiparticle pair (nothing special about muons) can be made as long as there is enough energy for $E = mc^2$.
- How do we choose, in the example above, to say if the electron-positron or the muon pair are the “basic” particles?

Building Blocks of matter?

In what sense should we now think of elementary particles as “building blocks” of matter?

- *They are not permanent constituents.*
- They are more like packets of conserved quantities. The packets can be repacked in different ways.
- We can think of the “particles” in Dirac theory as excitations of the fields of the vacuum.
- That’s one way to understand why electrons are truly identical- they aren’t so much “things” as modes of behavior of the vacuum. If a simple harmonic oscillator (mass on spring, SHO) has one quantum of energy (hf) above the ground state, we don't ask "which quantum of energy?" If it has 10 quanta, we don't ask "which one is first?" because the quanta just describe states of the oscillator, not some preexisting "things".

So our story has shades of the ether- but not an ether which prefers one reference frame!

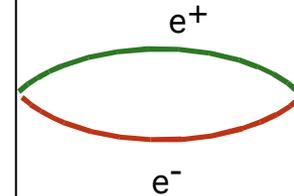

Carrying the SHO analogy farther

- An SHO can't just sit in the position of lowest potential energy. The Uncertainty Principle forces it to spread out some, so there's some potential and kinetic energy ($hf/2$) in the ground state. If you "look" with a beam of high-energy particles (i.e. "measure" the position you will not usually find it to be at the position of lowest potential energy.
- Likewise there is necessary uncertainty in the fields which specify how many particles/antiparticles of any type are present, even in the lowest energy state, i.e. the vacuum.
- The lowest energy state is not the one in which we can say with certainty that nothing is there. Rather, it is a superposition such that when we look we usually see nothing, but there is a nonzero probability of finding stuff there. The reason for this is that the quantities that describe electron-positron pairs are not all simultaneously measurable. (i.e. they're like position and momentum of SHO, or x and y spins of an electron)
- If there were definitely zero particles, then the values of all these quantities would be definite, in violation of the uncertainty principle.

Toy Pictures of the Vacuum

- It is tempting to think of the vacuum as being filled with particle-antiparticle pairs, blinking in and out of existence, vacuum “bubbles”:

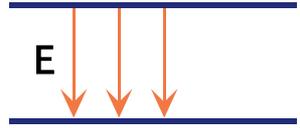

This isn't too bad an image, but be careful that what one actually measures depends on what experiment is done.
Nothing is really changing in time in the vacuum.

- How can a state with nonzero probability of the existence of an electron-positron pair (with $E=2m_0c^2$) possibly be lower energy than a state without it?
- The uncertainty principle has a time component that is similar to the space component:

$\Delta p \Delta x \geq \hbar / 2$	Space component
$\Delta E \Delta t \geq \hbar / 2$	Time component
$\Delta (mc^2) \Delta t \geq \hbar / 2$	Lorentz invariant form
- So on sufficiently short time scales, the mass (i.e. number of particle-antiparticle pairs) must become ill-defined. We call this uncertainty virtual particles. The fluctuations in more massive particle fields (bigger m 's) require smaller Δt 's.
- Virtual massive particles can only exist for shorter times and are thus more rare than less massive ones.

Does this view of the vacuum makes sense?

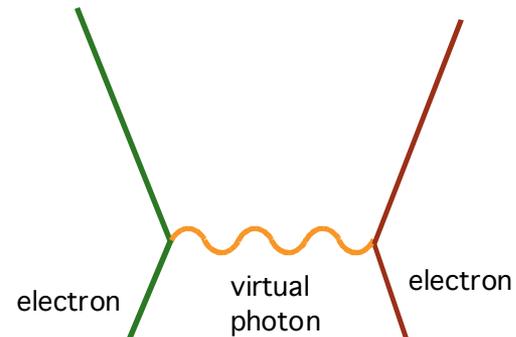

- **Sparking of the vacuum.** Consider a region of extremely strong electric field. If there is any residual gas in the gap, one is likely to get a spark. Suppose we have a **perfect vacuum**. The vacuum isn't empty, so if there is enough energy stored in the field, that energy can be transferred to the virtual pairs, making them real. The required electric field is enormous. This effect has only been seen in the electric field near super-heavy nuclei ($Z \sim 180$)
A diagram showing two parallel horizontal blue lines representing metal plates. Between the plates, three orange arrows point downwards, labeled with the letter 'E', representing the electric field.
- **The Casimir force:** Take two plates of metal near each other. They do not allow any long-wavelength E-M excitations in between. The lost excitations have positive energy. As the plates get closer, they eliminate more positive vacuum energy. Hence closer means lower net energy- so any two good conductors *attract* when they are nearby. (repeatedly measured, to fairly good precision)
- **Hawking radiation.** Near black holes, the gravitational field is very strong, and the energy stored in the field can be converted into particle pairs in a similar way. By this mechanism, black holes are predicted to “evaporate.” (The evaporation time for a solar mass BH is longer than the age of the universe.)

So empty space isn't.

- Combining SR and QM requires that the number of particles of some type be represented by a quantum field. It is therefore subject to uncertainty relations. We treat the vacuum as if it were filled with a sea of potentially existing particle-antiparticle pairs, giving a "zero-point energy", like the (measured) zero-point energies of SHO's.
- This treatment is not just hypothetical. The vacuum energy in the E-M field depends on confinement by conductors. Therefore a force is exerted on the conductors (the Casimir force). It's measurable, rather precisely.
- A force depends on differences in energy as a function of position. So measuring the Casimir force does not tell you the energy density of empty space, only how it changes when pieces of metal are moved around in it.
- Absolute energies (as opposed to differences) enter into physics as the masses which give rise to gravity. So we have to ask whether we can calculate the energy density in space that serves as a source of gravitational effects simply by adding up the sorts of background energies that give the Casimir effect.
- If we do so, we end up with an infinite energy density, just like in the old black-body radiation problem. That should be rather noticeable- e.g. in its effect on cosmology!
- Something is missing in our understanding of how to treat this problem.

Forces and Particles

- One can regard the EM force to be the result of the exchange of photons. For example, one can draw this picture to represent one electron bouncing off another one :
 - Conservation of energy and momentum does not allow the photon to be real
- Let's look at a force involving exchange of a particle with rest mass m .
 - $p^2c^2 = E^2 - m^2c^4$.
 - For long times, $E^2 = 0$, so $p^2 = -m^2c^2$. $p = imc$. That stands for an *exponentially decaying function* with range $\sim h/|p| = h/mc$. Forces corresponding to exchange of massive particles are short-ranged.
- Photons have no rest-mass, so the solution for the photon field is long-range; force falling off as $1/r^2$.

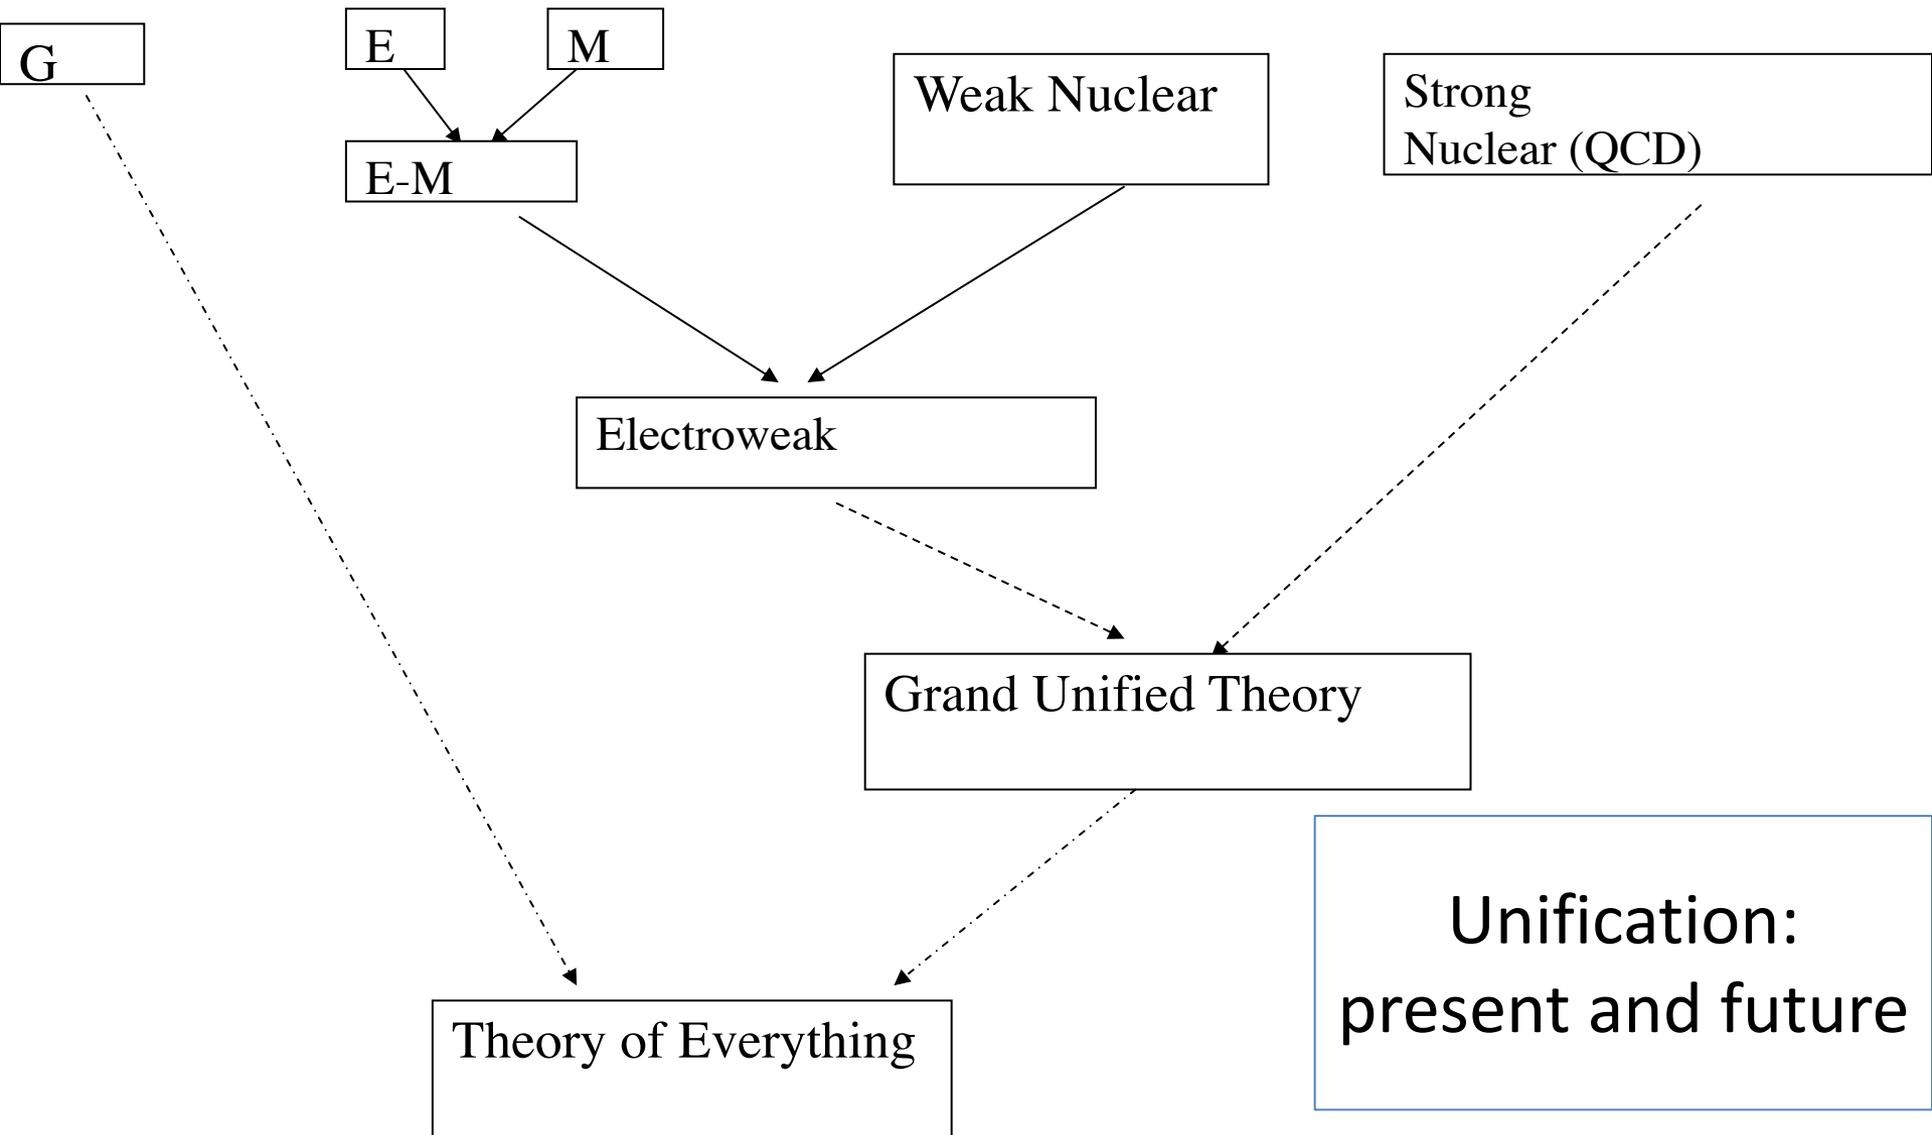

Forces and Particles

- There is no longer the old distinction between the fields that carry force and the particles that are acted on by these forces. They are all quantized fields, whose quanta are given particle-like names.
 - This is the completion of the process that began with the discovery of the particle-like properties of E-M radiation and of the wave-like properties of particles.
- The remaining distinction is between bosons and fermions.
 - Bosons (integral spin) can pile up in single-particle states, and make nearly classical fields.
 - Fermions (half-integral spin) are limited to one per state, and thus are more like classical "matter", of which people used to say "no two things can be in the same place at the same time."
 - This spin-statistics connection follows from a theorem based on SR+ QM, not just an observation.
- Although we've thought of bosons and fermions as entirely distinct, getting that vacuum-fluctuation energy to not blow up to infinity seems to require "supersymmetry"- boson/fermion pairs whose high-energy fluctuations cancel.
 - Not yet found.

Unification of forces

- There are four known forces:
 - gravity
 - strong nuclear (QCD)
 - electromagnetism (QED)
 - weak nuclear
- Except gravity, *all* the forces seen in elementary physics problems (sliding friction, static friction, normal, spring, rope, etc) are manifestations of QED. QCD binds the nucleons together; the weak nuclear force produces some radioactive decay.
- You've seen one unification already: electricity and magnetism. Those seemed like entirely separate phenomena from 500 BC to 1700 AD.
- Links between them were found:
 - Moving electric charges exerted forces on magnets.
 - Moving magnets exerted forces on electrical charges.
- The *unified* theory (Maxwell's equations) does more.
- It predicts the existence of a new type of wave: E-M waves. The properties of that wave (speed, polarization, energy density, momentum) all are *derived* from the theory unifying the forces. In this case, the predicted new wave wasn't so new- it was just light. In other cases, the predicted new waves/particles from unifications are usually new enough that one must do new experiments to find them.
- The unified theory is more than the sum of the parts.

Not yet established

Very hypothetical

Dis-Unification: the E&M example

- In atoms, electrical forces are much stronger than magnetic forces. At very high temperature (high enough so that relative velocities on the order of c are common) magnetic and electrical effects are of about the same size. In a world of charged particles flying around near speed c , it would not make sense to have separate treatments of "magnetic" and "electric" forces, since these would obviously be manifestations of the same effects. Remember that these fields transform into each other in Lorentz transformations.
- Magnetic and electric forces become separable only if you pick a particular reference frame in which most things aren't moving fast relative to each other. If the local environment strongly breaks the Lorentz symmetry of relativity, the forces look different. *In the full symmetry environment, they obviously belong to a unified theory.*
- These features- prediction of new particles, connection between symmetry loss and apparent disunity of forces- will be found in the other unifications, including the one fully achieved (electro-weak), the one with some serious proposals and experiments (grand unification), and perhaps the one in embryo ("theory of everything").

The “Standard Model” (1970s)

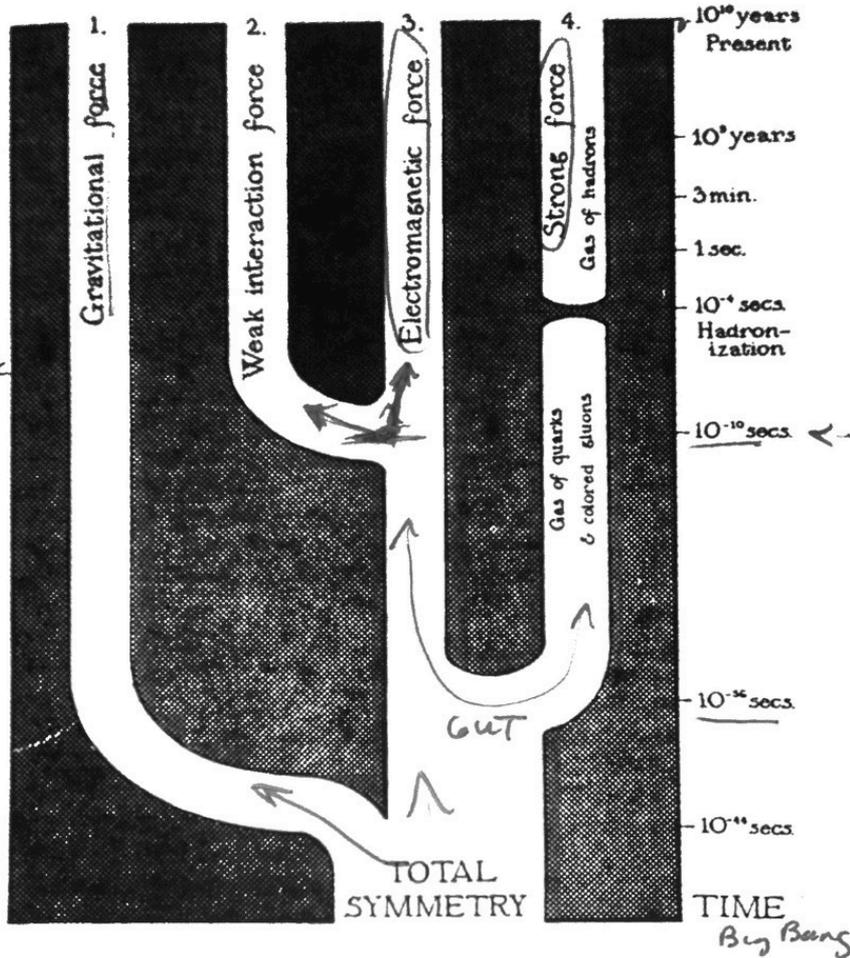

- Table shows the basic particles (61)
- 3 leptons and 3 quarks
- We never see free quarks
- Neutrons and protons are 3 quarks
- All particles have now been seen
- The interactions between the particles is mathematically simple but very difficult to “solve” except on big computers
- Almost complete agreement with all experiments. (0.02%)

BUT

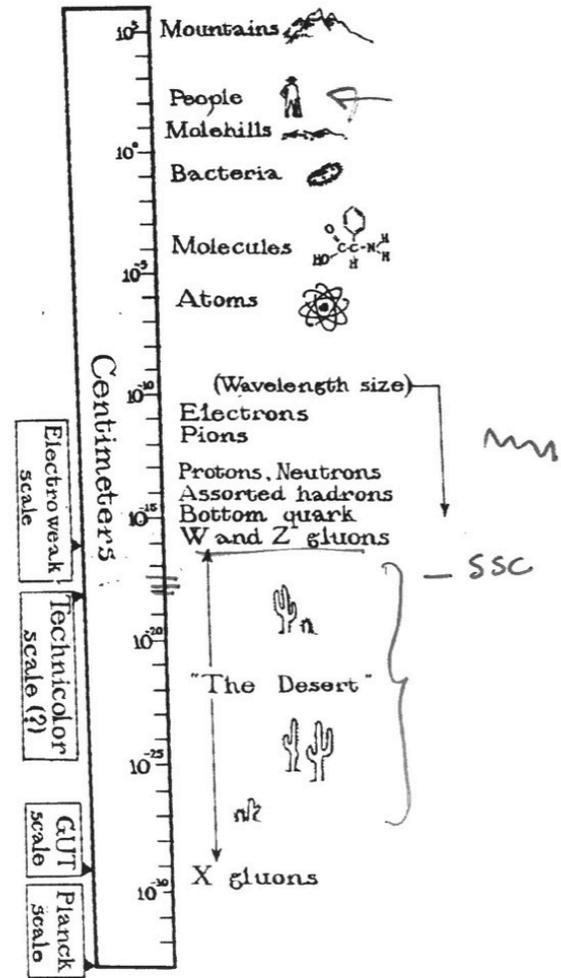

- Why so many parameters? (19)
- How to combine with gravity
- Are there more particles such as WIMPS for dark matter?
- Matter/antimatter imbalance.

	Fermions			Bosons	
Quarks	u up	c charm	t top	γ photon	Force carriers
	d down	s strange	b bottom	Z Z boson	
Leptons	ν_e electron neutrino	ν_μ muon neutrino	ν_τ tau neutrino	W W boson	
	e electron	μ muon	τ tau	g gluon	
				Higgs boson

FOUR FUNDAMENTAL INTERACTIONS

The evolution of the universe as a succession of broken symmetries. If the ideas of modern field theory are right and broken symmetries are restored at high temperature, then at the very earliest times the four known forces of nature, now seen as distinct, were unified.

The distance scales of the universe in powers of 10, from the Planck scale to the size of the universe. There may be a "desert" in the microworld. One of the main insights of modern physics is how the microworld influences the macroworld.

More unification

The electroweak interaction: EM and weak don't have much obviously in common:

- EM interactions depend on the electric charge, a conserved quantity. Weak interactions depend on another property (called weak isospin) that isn't conserved.
- EM interactions are long range ($1/r^2$). Weak interactions are short range ($\sim 10^{-18}$ m, decreasing exponentially).
- Some particles (*e.g.*, quarks) participate in EM, but not weak interactions, and some (*e.g.*, neutrinos) vice-versa.
- But there are similarities. Within its short range, the weak interaction is actually the *same strength* as EM. It has been known since 1935 (Yukawa) that the short-range forces are due to the exchange of *massive* particles. Therefore, in the late 1950s it was proposed that the weak interactions are mediated by heavy intermediate vector bosons, related to photons. **These have been found.**

GUT (grand unified theory)

- The next unification would be of the electroweak with the strong nuclear force, which is described by QCD (quantum chromodynamics). There are a variety of different proposals for GUT. Each involves distinct experimental predictions for new particles, how the strengths of the interactions depends on the length scale, etc. High-energy accelerator physics is largely concerned with finding the proper form of the GUT by sorting out these effects.

What about quantum gravity, i.e. QM +GR?

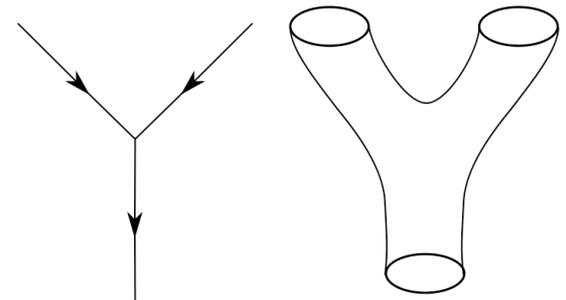

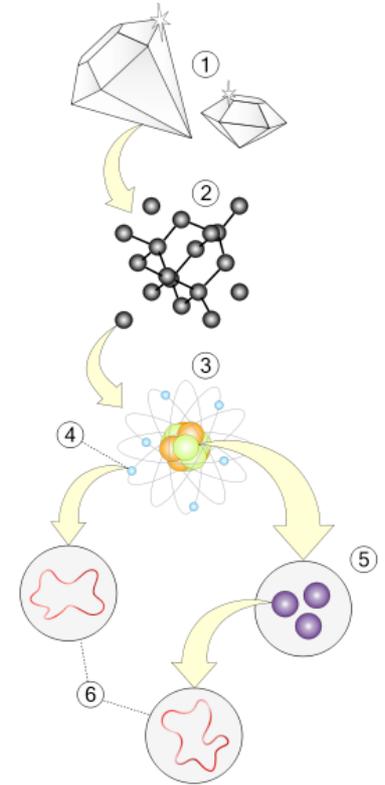

- The first of the fundamental forces to be found is the hardest to integrate into the unified framework of forces in QM. We know for sure that QM and GR don't combine in an obvious way- trying to simply quantize GR gives zero or infinity for any calculation
- The present form of GR and QM are *not consistent*, so there must be some deeper form which applies in the realm where quantum effects become important (very short times/distances, high energies).
- So far the main proposals that look like they have a chance to give GR in the usual regime without making contradictions in the high-energy regime are proposals involving more space-time dimensions: string theory and its relatives, theories of interactions in 10 or 11 space-time dimensions. This approach has not yet given a complete consistent theory- i.e. one where you can write down some complete axioms, and then calculate some predictions. (Other approaches include “loop quantum gravity.”)

QM + GR: not just inconsistent

- Reminder: When Einstein argued that a careful experiment could violate an uncertainty relation (and hence violate QM) Bohr showed that inclusion of GR effects preserved the uncertainty, and saved QM.
- But now we've heard that to preserve the QM framework, GR must be replaced on a small scale, and as an ultimate theory. What then will rescue the uncertainty relations on that small scale?
- Will it be necessary to replace *both* QM and GR? Will that help with the measurement question?

String Theory

- Generalization of quantum field theory. Hot topic of last 25 years
- Objects are not “points” but “loops”
- Particles are “vibrations” of the loops like tones on a guitar string.
- One of the modes is a graviton that causes gravity
- Open strings are photons.
- Space-time is in 10 dimensions. What happened to the other extra ones? Compactified so we cannot see them now.
- Latest version is M-theory in 11 dimensions. Can contain “branes”: (membranes): generalizations of strings to higher dimensions.
- Theory is more complicated, so there are fewer results

- **Successes (all disputed)**
 - Combines quantum mechanics and gravity
 - Can predict black hole properties
 - Explains why the universe is matter and not antimatter
 - What the dark matter is
 - Why quarks and leptons come in three similar families
 - Cosmological history of inflation, flat space-time
- **Problems**
 - Too many possible theories (10^{500} theories) One can get many physical laws. Each describes a different universe
 - Little or no experimental confirmation, energies too high (10^{14} times LHC@CERN), lengths too small.
 - Have not yet explained “standard model” details, too complicated, too many theories
