

Photon emission: $e^+e^- \rightarrow m^+m^-\gamma$

We now consider an $\mathcal{O}(\alpha)$ correction to the process we studied last week.

external photon polarization
↓

Assume $Q^2 = (p_1+p_2)^2 \gg m_m^2$ so we can ignore m_e, m_m .

$$iM = i \frac{e^2}{Q^2} \bar{v}(p_2) \gamma_\mu u(p_1) \bar{u}(p_3) \left[\gamma^\mu \frac{-i(\not{p}_4 + \not{p}_r)}{(p_4+p_r)^2} (-ie\gamma^\alpha) + (-ie\gamma^\alpha) \frac{i(\not{p}_3 + \not{p}_r)}{(p_3+p_r)^2} \gamma^\mu \right] v(p_4) \epsilon_\alpha^\beta(p_r)$$

internal fermion propagators defined with momentum along arrows, so need a minus sign here

$$\text{Let } S^{\mu\alpha} = -ie \left[\gamma^\alpha \frac{i(\not{p}_3 + \not{p}_r)}{(p_3+p_r)^2} \gamma^\mu - \gamma^\mu \frac{i(\not{p}_4 + \not{p}_r)}{(p_4+p_r)^2} \gamma^\alpha \right]$$

(not symmetric in μ and α ! watch index order!)

Cross section after averaging over initial and summing over final spins is

$$\sigma_r = \frac{1}{2Q^2} \int d\pi_3 \langle |M|^2 \rangle = \frac{e^4}{2Q^6} L^{\mu\nu} X_{\mu\nu}$$

\uparrow \uparrow \uparrow
 $v_1=v_2=1/2$ $Q^2=(2E_1)(2E_2)$ in CM frame w/ $E_1=E_2 = \frac{\sqrt{Q^2}}{2}$

$L^{\mu\nu}$ is left half of the diagram:

$$L^{\mu\nu} = \frac{1}{4} \sum_{s_1, s_2} \bar{v}(p_2) \gamma^\mu u_{s_1}(p_1) \bar{u}_{s_2}(p_1) \gamma^\nu v_{s_2}(p_2) = \frac{1}{4} \text{Tr}[\not{p}_2 \gamma^\mu \not{p}_1 \gamma^\nu] = p_1^\mu p_2^\nu + p_1^\nu p_2^\mu - \frac{1}{2} Q^2 g^{\mu\nu}$$

$X^{\mu\nu}$ is right half, involving the photon:

from $(\bar{u} \gamma^{\mu_1} \dots \gamma^{\mu_n} v)^+ = \bar{v} \gamma^{\mu_n} \dots \gamma^{\mu_1} u$

$$X^{\mu\nu} = \int d\pi_3 \sum_{\substack{s_3, s_4 \\ \text{pols.}}} \left[\bar{u}_{s_3}(p_3) S^{\mu\alpha} v_{s_4}(p_4) \bar{v}_{s_4}(p_4) S^{\beta\nu} u_{s_3}(p_3) \epsilon_\alpha^\beta(p_r) \epsilon_\rho(p_r) \right]$$

Use $\sum_{\text{pols.}} \epsilon_\alpha^\beta(p_r) \epsilon_\rho(p_r) \rightarrow -\eta_{\alpha\rho}$: $X_{\mu\nu} = - \int d\pi_3 \text{Tr}[\not{p}_3 S^{\mu\alpha} \not{p}_4 S^{\beta\nu}]$

apologies for bad index height:
Useful abuse of notation here

Here, we are integrating over 3-body phase space,

$$d\pi_3 = \frac{d^3p_3}{(2\pi)^3} \frac{d^3p_+}{(2\pi)^3} \frac{d^3p_-}{(2\pi)^3} \frac{1}{2E_3} \frac{1}{2E_+} \frac{1}{2E_-} (2\pi)^4 \delta(Q - p_3 - p_+ - p_-)$$

where $Q = p_1 + p_2$.

Let's put off actually calculating $X^{\mu\nu}$ for a bit and see what the cross section looks like for a generic final state.

By the Ward identity, we know $Q_\mu X^{\mu\nu} = 0$. After phase space integration, X is a function of Q only, and symmetric in $\mu \rightarrow \nu$ (because $L^{\mu\nu}$ is),

$$\text{So } X_{\mu\nu} = (Q_\mu Q_\nu - Q^2 \eta_{\mu\nu}) X(Q^2)$$

only symmetric tensors
built out of Q

↑
Scalar function
of Q^2

In this form, $\eta^{\mu\nu} X_{\mu\nu} = (Q^2 - 4Q^2) X(Q^2)$, so $X(Q^2) = -\frac{1}{3Q^2} \eta^{\mu\nu} X_{\mu\nu}$

Plug in for $L^{\mu\nu}$: $L^{\mu\nu} X_{\mu\nu} = (p_1^\mu p_2^\nu + p_1^\nu p_2^\mu - \frac{1}{2} Q^2 \eta^{\mu\nu}) (Q_\mu Q_\nu - Q^2 \eta_{\mu\nu}) X(Q^2)$
 $= (2(p_1 \cdot Q)(p_2 \cdot Q) - \frac{1}{2} Q^4 - 2Q^2(p_1 \cdot p_2) + 2Q^4) X(Q^2)$

Now, $Q^2 = (p_1 + p_2)^2 = 2p_1 \cdot p_2$ (assuming $m_e = 0$), and similarly,

$$p_1 \cdot Q = p_1 \cdot (p_1 + p_2) = p_1 \cdot p_2 = \frac{Q^2}{2} = p_2 \cdot Q$$

$$L^{\mu\nu} X_{\mu\nu} = (2(\frac{Q^2}{2})(\frac{Q^2}{2}) - \frac{1}{2} Q^4 - Q^4 + 2Q^4) X(Q^2) = Q^4 X(Q^2) = -\frac{Q^2}{3} \eta^{\mu\nu} X_{\mu\nu}$$

$$\Rightarrow \sigma_r = \frac{e^4}{2Q^6} L^{\mu\nu} X_{\mu\nu} = -\frac{e^4}{6Q^4} \eta^{\mu\nu} X_{\mu\nu}$$

Recall from last week that $\frac{d\sigma_{e^+e^- \rightarrow \mu^+\mu^-}}{d\theta} = \frac{e^4}{32\pi Q^2} (1 + \cos^2\theta)$, so integrating over θ ,

$$\sigma_0 \equiv \sigma_{e^+e^- \rightarrow \mu^+\mu^-} = \frac{e^4}{12\pi Q^2}$$

Thus we can write $\sigma_r = \sigma_0 \left(-\frac{2\pi}{Q^2} \eta^{\mu\nu} X_{\mu\nu} \right)$.

There is a nice way to interpret this result. Let's write

$$\sigma_r = \frac{4\pi\sigma_0}{Q} \times \frac{1}{2Q} x^{\mu\nu} (-\eta_{\mu\nu}), \text{ where } Q = \sqrt{Q^2}. \text{ The decay rate}$$

of a particle of mass M is given by $\Gamma = \frac{1}{2M} \int d\pi \langle |M|^2 \rangle$.

So we can interpret the rate for $e^+e^- \rightarrow \mu^+\mu^- \gamma$ as the product of the rate for $e^+e^- \rightarrow \gamma^*$, a virtual photon of mass Q , times the decay rate of that photon, $\gamma^* \rightarrow \mu^+\mu^- \gamma$, summed over polarizations of the final-state photon. This is a special case of the narrow-width approximation, which is a general statement about the factorization of Feynman diagrams through an intermediate state. We will see this again when we study weak interactions.

Let's parameterize the phase space of $\gamma^* \rightarrow \mu^+\mu^- \gamma$ using Mandelstam variables as

$$s = (p_3 + p_4)^2 \equiv Q^2(1-x_r)$$

$$t = (p_3 + p_r)^2 \equiv Q^2(1-x_1)$$

$$u = (p_4 + p_r)^2 \equiv Q^2(1-x_2)$$

From HW 4, $s+t+u = \sum m_i^2 \approx Q^2$ (you derived it for $p_1+p_2 \rightarrow p_3+p_4$, but a similar result holds with appropriate minus signs for $Q \rightarrow p_3+p_4+\gamma$)

$\Rightarrow x_r+x_1+x_2 = 2$, take $x_r = 2-x_1-x_2$ so x_1 and x_2 are independent.

Limits of integration: $t = 2p_3 \cdot p_r = 2E_3 E_r (1 - \cos\theta_{3r})$. $t_{\min} = 0$ when $E_r = 0$;

$t_{\max} = 4E_3 E_r$ when $\cos\theta_{3r} = -1$. If $E_4 = 0$, $E_3 = E_r = \frac{Q}{2}$, so $t_{\max} = Q^2$

$$\Rightarrow x_{1,\min} = 0, x_{1,\max} = 1$$

$$\int d\pi_3 = \frac{Q^2}{128\pi^3} \int_0^1 dx_1 \int_{1-x_1}^1 dx_2 \quad (\text{recall very similar form from HW 3})$$

$$\text{Tr}[\not{p}_3 \not{S}^{\mu\alpha} \not{p}_4 \not{S}^{\alpha\nu}] = \frac{8e^2(x_1^2 + x_2^2)}{(1-x_1)(1-x_2)} \quad (\text{A1HW extra credit})$$

This diverges logarithmically ($\int \frac{1}{x} dx$) at $x_1, x_2 = 1$.

By the analysis above, $x_1 = 1$ corresponds to $2E_3 E_r (1 - \cos \theta_{3r}) = 0$.

This can happen either if $E_r = 0$ (a soft singularity), or $\theta_{3r} = 0$ (a collinear singularity). This behavior is generic in QFT: massless particles prefer to be emitted with low energies and along the directions of charged particles.

If we pretend that the photon has a mass m_γ , and let $\beta = \frac{m_\gamma^2}{Q^2}$, the limits of integration change to $\int d\pi = \int_0^{1-\beta} dx_1 \int_{1-x_1-\beta}^{1-\frac{\beta}{1-x_1}} dx_2$ (HW)

Doing the integral, $\int_0^{1-\beta} dx_1 \int_{1-x_1-\beta}^{1-\frac{\beta}{1-x_1}} dx_2 \frac{x_1^2 + x_2^2}{(1-x_1)(1-x_2)} = \ln^2 \beta + 3 \ln \beta - \frac{\pi^2}{3} + 6$

double logarithms from x_1 and x_2 (or soft and collinear)

However, these singularities are not physical! It turns out they cancel exactly against the interference terms from

The result is $6 - \frac{\pi^2}{3} \rightarrow \frac{3}{2}$ for the finite pieces, so

$$\Gamma(\gamma^0 \rightarrow \mu^+ \mu^- \gamma) = \frac{e^2}{2Q} \frac{Q^2}{128\pi^3} \left(8 \times \frac{3}{2}\right) = \frac{3Qe^2}{64\pi^3}$$

$$\sigma_{\text{tot}} = \sigma_0 + \frac{4\pi\sigma_0}{Q} \frac{3Qe^2}{64\pi^3} = \sigma_0 \left(1 + \frac{3e^2}{16\pi^2}\right)$$

quantum correction to $\mu^+ \mu^-$ inclusive production cross section (0 or 1 photon)

What this result tells us is that $e^+e^- \rightarrow \mu^+ \mu^-$ with an arbitrarily low energy photon, or one emitted along one of the muon directions, is indistinguishable from just $\mu^+ \mu^-$ in the final state.

Charged particles are accompanied by clouds of photons.

More concrete interpretation: any real experiment will have a finite energy resolution E_{res} and angular resolution θ_{res} . Instead of cutting off the integral with m_V , use E_{res} and θ_{res} instead.

This is technically complicated, so we will just quote the answer:

$$\sigma(e^+e^- \rightarrow \mu^+\mu^- \gamma) \Big|_{\substack{E_V > E_{res} \\ \theta_{\mu} > \theta_{res}}} = \sigma_0 \frac{e^2}{8\pi^2} \left(\ln \frac{1}{\theta_{res}} \left[\ln \left(\frac{Q}{2E_{res}} - 1 \right) + \dots \right] + \dots \right)$$

exclusive cross section (exactly 1 photon)

Focus on $\ln \frac{Q}{2E_{res}}$. If $Q \gg E_{res}$, could be in a situation where

$$\ln \left(\frac{Q}{2E_{res}} \right) > \frac{8\pi^2}{e^2}, \text{ and perturbation theory breaks down.}$$

Solution: Consider $e^+e^- \rightarrow \mu^+\mu^- + N\gamma$, and don't restrict to a fixed number of photons. This is no longer at a fixed order in the coupling e , but corresponds better to the physical situation where distinguishing 2 vs. 3 vs. 4 very low-energy photons isn't possible in practice. *Inclusive cross sections often have better convergence properties.*

**HW: emission of photon from initial state.*

Lessons from this week:

- QFT gives infinities when you ask it dumb (unphysical) questions. By relating amplitudes to a physically measurable quantity, we always get finite results.
- Singularities tend to appear beyond the lowest-order diagrams. Resolving them may require summing over several amplitudes coherently.
- Not all loop diagrams suffer from this complication: electron magnetic moment is one example.
